INDEX

NAME INDEX

DERHALDEN, Prof. Emil, appointed president of the German Academy of Natural Sciences at Halle for nother ten years, 409
on, Viscount, *obituary* by Sir Edward Mellanby, 43
am, Dr. E. P., Baker, W., Chain, Dr. E., Florey, Prof. W., Holiday, E. R., and Robinson, Sir Robert, Nitroenous Character of Penicillin, 356
ham, Dr. E. P., and Chain, Dr. E., Purification of Penicillin, 328
rahams, Miss M., Canteen Feeding, 685
amowitz, Rosaline K. (Loufbourow, Prof. John R., Webb, Dr. Alfred M., and), Relation of Aeration to the tivity of Proliferation-Promoting Factors from Injured lls, 272
on, E. G., 'Aquadag', 298
ey, R. O., elected president of the Illuminating gineering Society, 576
Prof. E. D., visit to the Argentine, 576; awarded e Order of Merit, 692
ising Service Guild, An Inquiry into British War Production, Part I: People in Production (Report prepared by Mass-Observation), review, 711
, Alexander Gode-von, Natural Science in German omanticism, *review* by Prof. A. Wolf, 104
Agashe, Prof. D. S. (Diwan, G. S., and), Differential Equations, eview, 125
Agduhr, Prof. Erik, Hormonal Increase of Resistance and its Mechanism, 171
Akenhead, D., Index to the first ten volumes of *Horticultural Abstracts*, 19
Albano, V. J., Environmental Factors in Corrosion, 223
Albert, Dr. Adrien, and Goldacre, Dr. Reginald, Relative Acidity and Basicity of Sulphanilamide and *p*-Aminobenzoic Acid, 245
Albert, Prof. C. D., Machine Design Drawing Room Problems, third edition, *review*, 205
verque, Prof. J. P., *death* of, 72; *obituary* by Sir rnon Aspinall, 213
, J. N., Fluorescent Light Sources, 466
Leander McCormick Proper Motions, 142
Dr. Clifford, A Mystical Psychology, *review*, 622
G. W., Polarization of the Corona, 53
P., A Wealden Soil Bed with *Equisetites lyelli* ndell), 474
C., appointed veterinary officer, Nigeria, 217
e, Dr. T. E., Research on Electrical Surges, *review*, 621
George, Galactic Absorption and Apparent Distribuof Spectral Types, 360
George, and Edwards, D. L., XZ Aurigæ, an *N*-Type able, 25
rof. E. H., appointed provost of Trinity College, blin, 578
Amadon, C. H., Lodgewood Telegraph Poles, 467
Anderson, Dr. E. M., The Dynamics of Faulting and Dyke Formation, with Applications to Britain, *review* by Prof. O. T. Jones, 651
Anderson, Sir John, elected to the Athenæum, 75
Andrade, Prof. E. N. da C., *obituary* of Sir William Bragg, 346
Angold, F. H., The Anthropological Approach to the Study of Music, 186
Angus, Dr. W. Rogie, Magnetochemistry, *review*, 396
Angwin, Sir Stanley, Post-War Planning in Radio Telecommunication, 614
Appleton, Sir Edward, Progress of Geomagnetism, *review*, 177; to deliver the twenty-sixth Guthrie Lecture of the Physical Society, 299; *obituary* of Sir William Bragg, 348
Arctowski, Dr. H., Solar Radiation and Atmospheric Temperature, 276
Armstrong, Dr. E. F., Plastics and their Use, *review*, 682
Armstrong, Major Edwin H., awarded a John Scott Medal and Premium of the American Philosophical Society, 243
Armstrong, Major Harry G., given the John Jeffries award of the American Institute of the Aeronautical Sciences, 469
Arrol, W. J., Jacobi, R. B., and Paneth, Prof. F. A., Meteorites and the Age of the Solar System, 235
Aschner, M., Avineri-Shapiro, S., and Hestrin, Dr. S., Enzymatic Synthesis of Levan, 527
Ashby, Dr. Maurice, British Empire Drug Production, 225
Aspinall, Sir Algernon, *obituary* of Prof. J. P. d'Albuquerque, 213
Astbury, Dr. W. T., *obituary* of Sir William Bragg, 347
Aston, Dr. F. W., Mass Spectra and Isotopes, second edition, *review* by Prof. James Kendall, 680
Asundi, Prof. R. K., Singh, Nand Lal, and Singh, Jag Deo, A Reversible Discharge Tube, 22
Attwooll, K. W. (Marshall, J. F., and), Breeding of Mosquitoes in Static Water Supplies, 352
Audsley, A., and Goss, F. R., Solvent Effect and Dipole Moments, 276
Austin, G. J., Adsorption of Metals of the Iron Group in Analysis, 276
Avineri-Shapiro, S. (Aschner, M.), and Hestrin, Dr. S., Enzymatic Synthesis of Levan, 527
Awbery, J. W., Carl von Linde, a Pioneer of 'Deep' Refrigeration, 630
Ayres, William L. (Wilder, Raymond L., and), edited by, Lectures in Topology, the University of Michigan Conference of 1940, *review* by Prof. H. T. H. Piaggio, 396
Aziz, Abdulazim, Luminous Phenomenon accompanying the Cyprus Earthquake, January 20, 1941, 640

BABCOCK, H. W., and Johnson, J. J., Spectrophotometry of the Night Sky, 114
Bach, S. J., Dixon, Dr. Malcolm, and Keilin, Prof. D., A New Soluble Cytochrome Component from Yeast, 21
Bach, S. J., Dixon, Dr. Malcolm, and Zerfas, Dr. L. G., Lactic Dehydrogenase of Yeast, 48
Bacharach, A. L., Green Leaves as a Source of Proteins, 251; Physiology of the Amino Acids, 473; Canteen Feeding, 685
Bacharach, A. L., and Coates, M. E., Biological Estimation of Vitamin P Activity, 474
Baconi, Rogeri, Opera hactenus inedita, Fasc. 16: Communia Mathematica Fratris Rogeri, Partes prima et seconda, Nunc primum edidit Dr. Robert Steele, *review*, 125
Badger, G. M., et *al.*, Inhibition of Growth by Chemical Compounds, 275
Bagnall, D. J. T., Colours in Food, 537
Baguley, P. W. (Perry, F. R., Webster, G. H., and), The Measurement of Lightning Voltages and Currents in Nigeria, Part 2, 1938–1939, 198
Bailey, C. E. G., Radio Research and the War, 617
Baird, J. L., Television in Colour and Stereoscopic Relief, 18
Bairstow, S. awarded the Herbert Jackson Prize for 1941, 299
Baker, Frank, Normal Rumen Microflora and Microfauna of Cattle, 220; Microbial Synthesis and Autolysis in the Digestive Tract of Herbivora, 582
Baker, Prof. J. F., Design of Protective Structures and the Defence of Industry, 673
Baker, Dr. J. N. L., Halley's Work as a Geographer, 56; Historical Geography—Then and Now, *review*, 103
Baker, Dr. John R., Chemical Composition of Mitochondria, 611
Baker, Dr. L. C. (Lampitt, Dr. L. H., and), Ascorbic Acid in Oranges, 271
Baker, Dr. L. C. (Lampitt Dr. L. H., Parkinson, Dr. T. L., and), Disappearance of the Ascorbic Acid in Raw Cabbage after Mincing or Chopping, 697

Baker, R. T., *death* of, 20
Baker, W., Hexamethoxybenzene, 52; Derivatives of Pentahydroxybenzene, 141
Baker, W. (Abraham, Dr. E. P., Chain, Dr. E., Florey, Prof. H. W., Holiday, E. R., and Robinson, Sir Robert), Nitrogenous Character of Penicillin, 356
Baker, W. E. Watson, elected president of the Quekett Microscopical Club, 409
Baker, W. O., Toughness, Strength and Flexibility of Plastics, 504
"Balbus", Reconstruction and Peace, 338
Baly, Prof. E. C. C., Quantum Efficiency of Photosynthesis, 218
Bamford, Dr. C. H., Chemistry and Light, *review*, 714
Bancroft, Dr. Helen (Mrs. Simmons), interned at Vittel, 498
Barber, Dr. Harold Hayden, Physiology for Pharmaceutical Students, second edition, *review* by Prof. Samson Wright, 61
Barcroft, Sir Joseph, Food Production and Nutrition, 318; *obituary* of Prof. L. J. Henderson, 374
Barker, Tom, Soviet Metallurgy, 578
Barou, N., Post-War Agricultural Reconstruction, 372
Barrett, W. H. (Locket, G. H., and), Determination of Water in Soils, 612
Barron, Dr. Harry, Contribution to the Science for Victory Conference of the Association of Scientific Workers (Southern Area Committee), 617
Bartels, Prof. Julius (Chapman, Prof. Sydney, and), Geomagnetism, *review* by Sir Edward Appleton, 177
Bartley, Dr. S. Howard, Mechanisms of Vision, 40
Barton, W. C., *obituary* of Rev. H. J. Riddelsdell, 376
Barton-Wright, Dr. E., Microbiological Assay of Riboflavin in Cereals, 696
Baskett, R. G. (Bolton, W., and), Relative Firmness of Pig Back Depot Fat, 670
Bastin, Prof. Edson S., Aspects of Modern Geology, 26
Bawden, F. C., Crystallography and Plant Viruses, 321
Baynes, H. G., Domination or Relationship? *review*, 203
Bayon, Dr. H. P., The Significance of the Demonstration of the Harveyan Circulation by Experimental Tests, 326
Beadle, G. W., and Tatum, E. L., Physiological Genetics of Neurospora, 249
Beadnell, Surgeon Rear-Admiral Charles M., The Problem of the Autonomy of Life, 551; The Origin of the Kiss and other Scientific Diversions, *review* by T. Raymont, 713; Dictionary of Scientific Terms as used in the various Sciences, second edition, revised, and with Supplement, *review* by T. Raymont, 713
Beattie, A. G., appointed deputy director of agriculture, Nigeria, 694
Beavis, E. A., Cable Breakdowns due to Bomb Damage, 435; Thermal Breakdown in Supertension Cables, 737
Becker, Denis, A Sling against the Philistines, the New Machinery of Government by the People, 105
Beckinsale, S., Insulating Oils for Cables, 703
Beebe, William, Young Pacific Sailfish, 113
Beebe, William, and Tee Van, John, Rays and their Allies from the Eastern Pacific, 113
Beharrell, J., Seaweed as a Food for Livestock, 306
Beirne, B. P., Microlepidoptera of Ireland, 52
Belkengren, R., Nier, A. O., and Burr, G. O., Heavy Carbon Isotope in Plant Metabolism, 24
Bell, A. E., Hypotheses Non Fingo, 238; Modern Science and Thomas Hobbes, 688
Bell, D. A., and Hughes, Dr. L. E. C., Post-War Planning in Radio Telecommunication, 615
Bell, R. P., Acid-Base Catalysis, *review* by Prof. M. Polanyi, 103
Bellamy, Miss E. F., International Seismological Summary, July–September 1934, 380
Bennett, E. F., A Review of Driers and Drying, *review*, 425
Benson, J. E., Piezo-Electro Crystal Filters, 20
Berenblum, Dr. I., and Schoental, R., Metabolic Products of 3:4-Benzpyrene, 439
Berkeley, C., Occurrence of Ctenodrilus in the Pacific, 248
Berkeley, Earl of, *death* of, 133; *obituary* by Sir William Dampier, 163
Bernacchi, Lieut.-Comdr. L. C., *death* of, 496; *obituary* by Prof. Frank Debenham, 520
Bernal, Prof. J. D., Science and the War Effort, 71; Use of Science and Scientific Workers in the War, 132; Physical Science in the U.S.S.R., 545; Effect of High Explosives on Structures, 673
Bernal, Prof. J. D., and Fankuchen, Dr. I., Viruses and Crystallography, 321
Berridge, N. J., The Second Phase of Rennet Coagulation, 194
Betz, F., and Hess, H., Submarine Contours of the North Pacific, 359
Bhatia, Dr. M. L., Hirudinaria, the Indian Cattle Leech, 437
Bhattasali, N. K., Antiquity of the Lower Ganges and its Courses, 468
Bičanić, Dr. R., Post-War Agricultural Reconstruction, 372
Biddle, A. J., Drexel, Post-War Agricultural Reconstruction, 372
Bielschowsky, F., and Green, Prof. H. N., 2-Aminofluorene as Growth Inhibitor for Bacteria and Rats, 526, *erratum*, 607
Biggs, C. E. J., appointed deputy director of agriculture, Tanganyika, 607
Bilham, P., Jones, E. R. H., and Meakins, R. J., Surface Films of Lupane Derivatives, 415
Bilmes, L., Classification of Rheological Properties, 702
Bilmes, L. (Broome, Dr. D. C., and), 'Firmness' in Compression and Tension, 412
Birch, F. H. (Casson, W., and), The Management of Protective Gear on Power Supply Systems, 165
Bird, E. J. (McAlpine, R. K., and), Atomic Weights of Silver, Bromine and Potassium, 305
Bisat, W. S., awarded the Lyell Medal of the Geological Society of London, 135
Bishop, H., Technical Developments in Broadcasting, 269; Post-War Planning in Radio Telecommunication, 615
Black, Prof. Newton Henry, An Introductory Course in College Physics, revised edition, *review*, 9
Black, Richard H., Scientific Results of the United States Antarctic Expedition, 1939–41, 318
Blackett, Prof. P. M. S., elected to the Athenæum, 327
Blackman, G. E., appointed secretary of the Biology War Committee, 234
Blackwelder, Prof. Eliot, Science and Human Prospects, *review* by F. S. Marvin, 623
Blackwell, Elizabeth (Madge, Dr. Margaret A. P., and), Heterothally and Reproduction in Fungi, 440
Blair, Dr. G. W. Scott, Classification of Rheological Properties, 197, 702; conferment of the degree of D.Sc. of the University of London, 270
Blair, Dr. G. W. Scott, and Coppen, F. M. V., Psycho-Physical Significance of the Dissipation Coefficient of Soft Materials, 22
Blair, Dr. G. W. Scott, Cowie, A. T., and Coppen, F. M. V., Rheological Properties of Secretions from the Cervix of Pregnant and Non-pregnant Cows, 609
Blair, Dr. G. W. Scott, and others, Elasticity of Bovine Cervical Mucus, 222
Blake, Archie, Progress Report on Periodicity and Time Series, 308
Blakeslee, Dr. A. F., Individuality and Science, 288
Bledisloe, Lord, Better Dissemination of Scientific Knowledge among British Farmers, 722
Blewett, M. (Fraenkel, Dr. G., and), Biotin as a Possible Growth Factor for Insects, 301
Blumlein, A. D., Post-War Planning in Radio Telecommunication, 615
Bogart, R., and Muhrer, M. E., Hæmophilia-like Conditions in Pigs, 641
Bollinger, Dr. A., Effect of Chorionic Gonadotropin on the Pouch of the Marsupial *Trichosurus vulpecula*, 440
Bolton, K., Cullingworth, J. E., Ghosh, B. P., and Cobb, J. W., Gaseous Products of Carbonization, 700
Bolton, W., and Baskett, R. G., Relative Firmness of Pig Back Depot Fat, 670
Bonacina, L. C. W., Scenic Approach to Meteorology, 326
Bonn, A. E. (Crumb, S. E., Eide, P. M., and), The European Earwig in America, 141
Booth, Dr. R. G., Canteen Feeding, 685
Booth, V. H., Green Leaves as a Source of Proteins, 251

Bor, Dr. N. L., Common Grasses of the United Provinces, 199; New Descriptions of some Indian Plants, 417

Born, Prof. Max, Lonsdale, Dr. Kathleen, and Smith, H., Quantum Theory and Diffuse X-Ray Reflexions, 402

Borremans, M. L., Post-War Agricultural Reconstruction, 372

Boscovich, Roger Joseph, *review* by Prof. H. C. Plummer, 180

Bose, Dr. D. M., and Choudhuri, Miss Bibha, A Photographic Method of Estimating the Mass of the Mesotron, 302

Boughey, A. S., Cotton Seed Disinfection in War-time, 50

Bourne, Dr. Geoffrey, Feeding Post-War Europe, 182, *erratum*, 217; Nutrition and the War, second edition, *review* by Dr. S. K. Kon, 453, 666

Bowdler, G. W., Impulse Voltage Measurements, 701

Bowen, E. J., Reversible Quenching by Oxygen of the Fluorescence of Polycyclic Hydrocarbons, 528; The Chemical Aspects of Light, *review* by Dr. C. H. Bamford, 714

Bowen, J. Leonard, Reflexion from Paper, 733; Origins of Human Graphic Art, 733

Bowie, Dr. J. A., The Basis of Reconstruction, 337

Bowman, Prof. H. L., *death* of, 496; *obituary* by R. C. Spiller, 662

Bowyer, William, Brought Out in Evidence, *review* by Prof. W. G. de Burgh, 315

Bozorth, R. M., and Williams, H. J., Torque on a Silicon Iron Crystal in a Magnetic Field, 359

Bozorth, R. M. (Williams, H. J.), and Christensen, —., Magnetostriction in Permalloy, 359

Brabazon of Tara, Lord, Simplification of Musical Notation, 554

Bracey, R. J., A Multi-purpose Collimator, 324

Brackenbury, Sir Henry, *death* of, 297

Bragg, Sir Lawrence, The X-Ray Microscope, 470; The History and Development of X-Ray Analysis, 504; A Theory of the Strength of Metals, 511; Physicists during and after the War, 634; elected President of the Electronics Group of the Institute of Physics, 635

Bragg, Sir William, Science Lifts the Veil, 108; *death* of, 323; *obituary* notices by Prof. E. N. da C. Andrade, Dr. W. T. Astbury, Sir Henry Dale, Sir Edward Appleton, Sir Richard Gregory, Lord Cherwell, Major Charles E. S. Phillips, Prof. Allan Ferguson, Prof. J. A. Crowther, Dr. Kathleen Lonsdale 346; Tributes to, 352; *obituary* by A Free French Scientist, 406; The Story of Electromagnetism,, *review*, 425

Brailsford, F., and Martindale, R. G., Magnetostriction, 701

Branson, Prof. E. B., and Tarr, Dr. W. A., Introduction to Geology, second edition, *review*, 681

Brashear, John Alfred, Scientist and Humanitarian, 1840–1920 (Gaul, Harriet A., and Eiseman, Ruby), *review* by Dr. H. Spencer Jones, 283

Bratby, Michael, and Scott, Peter, Through the Air, Adventures with Wild Fowl, and Small-boat Sailing, *review* by Seton Gordon, 564

Braunholtz, H. J., *obituary* of Captain T. A. Joyce, 322

Brearley, Harry, Knotted String, Autobiography of a Steel Maker, *review* by Dr. C. H. Desch, 397; elected to honorary membership of the Iron and Steel Institute, 578

Brenchley, Dr. W. E., and Warington, Dr. K., Value of Molybdenum for Lettuce, 196

Brend, Dr. William A., Nervous Shock in Peace and War, 324

Breuil, Abbé H., Pleistocene Raised Beaches on the West Coast of Morocco, 77

Brewer, Dr. A. K. (Lasnitzki, Dr. A., and), An Isotopic Shift of Potassium in Human Bone-marrow and Cancer, 357

Bridgman, Prof. P. W., The Nature of Thermodynamics, *review* by Prof. E. A. Milne, 368

Brightman, R., Economics in the U.S.S.R., *review*, 681

Brimble, L. J. F., Biology as a Social Science, 457

Brink, R. A., and Cooper, D. C., Somatoplastic Sterility, 141

Bristow, J. R., Mechanism of Kinetic Friction, 169

Bristowe, Dr. William Syer, The Comity of Spiders, Vol. 2, *review* by T. H. Savory, 258

British Drug Houses, Ltd., The Colorimetric Determination of Oxidation-Reduction Balance, third edition, 299

Broatch, Miss M. C., Canteen Feeding, 685

Brobst, D. R., Cellulose Acetate Yarn for Wire Insulation, 437

Brodie, Harold J., and Neufeld, C. C., Mechanism of Germination of Conidia of Erysiphe, 332

Bronk, Detler W., Physical Instruments for the Biologist, 436

Brooks, Dr. C. E. P., Hurricane Floods of September 1938 in New England, 556

Brooks, Kenneth, Post-War Agricultural Reconstruction, 372

Broom, Dr. R., The Hand of the Ape-man, *Paranthropus robustus*, 513

Broome, D. C., Classification of Rheological Properties, 702

Broome, Dr. D. C., and Bilmes, L., 'Firmness' in Compression and Tension, 412

Brown, A. J., The Arsenal of Democracy, 522

Brown, Dr. Dugald E. S., Marsland, Dr. Douglas A., and Johnson, Dr. Frank H., awarded the nineteenth 1,000 dollar prize of the American Association for the Advancement of Science, 377

Brown, S. V., Science in Post-War Schools, 459

Bruce, C. E. R., and Golde, R. H., The Lightning Discharge, 224

Bruce, Hon. N. H. C., awarded the Cecil Peace Prize for 1941, 166

Brück, H. A., and Green, H. E., Radial Velocity Curve of δ Cephei, 333

Bruckshaw, Dr. J. M., Geophysical Methods in Geology, 690

Brunt, Prof. D., elected president of the Royal Meteorological Society, 189; An Introduction to Meteorology, *review*, 423

Bryant, G. E., Leaf-beetles Collected by Charles Darwin, 379

Bryant, Herwil F., Scientific Results of the United States Antarctic Expedition, 1939–41, 318

Zuckerman, Dr. S., Form and Character, *review*, 340; Embryology of the Rhesus Monkey, *review*, 592

TITLE INDEX

ABDOMINAL Viscera (Mammalian), Afferent Innervation of (Burns, W.), 221
Abnormality (A Useful) of the Pollen in a Pear (Thomas, Dr. P. T.), 168
Abortion, Bovine Contagious (Francis, F.), 663
Absorption (Emulsification and) of Fats and Paraffins in the Intestine (Frazer, A. C., Stewart, H. C., and Schulman, Dr. J. H.), 167
Absorption of Minimal Doses of β-Carotene by Vitamin A-Deficient Rats (Ramasarma, G. B., and Hakim, D. N.), 611
Abyssinia (Kenya and), Pleistocene Climates in (Kent, P. E.), 736
Acarapis, The mite (Schneider, Hans), 222
Acarine Disease of Bees, Frow Remedy for (Peterka, V., and Svoboda, J.), 222
Accident Proneness, Statistical Theory of (Chambers, E. G., and Yule, G. Udny), 466
Accuracy of a Few Observations in a Large Population (Stevens, W. L.), 700
Acetone, Photo-decomposition of (Spence, R., and Wild, W.), 114
Acidity and Basicity of Sulphanilamide and *p*-Aminobenzoic Acid, Relative (Albert, Dr. Adrien, and Goldacre, Dr. Reginald), 245
Action, Knowledge and, 647
Adaptation (Relict), Degeneration and (Huxley, Prof. Julian), 687
Adsorption of Metals of the Iron Group in Analysis (Austin, G. J.), 276
Adult Education as a Social Activity, 391
"Advancement of Science, The", No. 5, 189
Aeration (Relation of) to the Activity of Proliferation-Promoting Factors from Injured Cells (Loofbourow, Prof. John R., Webb, Dr. Alfred M., and Abramowitz, Rosaline K.), 272
Aeronautical Society, Royal, Mr. A. Gouge elected president for 1942–43, 729; Mr. E. F. Relf elected vice-president, 729; Dr. H. Roxbee-Cox elected vice-president, 729
Age Changes in Size of Muscle Fibres of the Marsupial Heart (Davies, Prof. Francis, and Francis, Dr. Eric T. B.), 410
Agricultural Advisers in Washington and London, 549
Agricultural Implications of a Food Policy based on Nutritional Needs (Orr, Sir John), 318
Agricultural Improvement Council for England and Wales, Committee on Hill Sheep Farming, 108
Agricultural Meteorology in India, 216
Agricultural Production, Planning for (Russell, Sir John), 318; Vernalization in (Gregory, Prof. F. G.), 209
Agricultural Reconstruction, Post-War (Jacks, G. V.), 372
Agricultural Scholarships (Ministry of Agriculture and Fisheries), 469
Agriculture, Food and, 208; on a National Scale (Russell, Sir John), *review*, 341; Research in (Walton, Dr. A.), 209; Science and Practice in, 722; after the War (Russell, Sir John), 12
Agriculture (European): Scientific Problems in Post-war Reconstruction, British Association Conference on, 189, 327
Agriculture, West Indian (Evans, Sir Geoffrey), 626
Agriculture and Fisheries (Ministry of), Agricultural Scholarships, 469; Sir George Stapledon appointed director of the Grassland Improvement Station, Dodwell, 549; Advisory Leaflet No. 246 on Silver Leaf Disease, 635; Scheme for the Control of Cattle Diseases, 663
Agriculture's Challenge to the Nation (Smith, Arthur), *review* by Sir John Russell, 341
Aids (Scientific) for the Layman, *review* by T. Raymont, 713
Air, Physics of the (Humphreys, Dr. W. J.), third edition, *review*, 8
Air Ministry, Meteorological Research Committee, 544
Air Navigation, Aids to (Jones, Dr. H. Spencer), *review*, 450
Air Navigation Stars, The Observer's Planisphere of (Chichester, Ft. Lieut. Francis), *review* by Dr. H. Spencer Jones, 450
Aircraft Defence against Barrage Balloon Cables, 73
Aircraft Instruments (Irvin, George Ellis), *review*, 593
Air-raid Damage, at University College, Exeter, 636; and Electricity Supply, 173, 362, 435
Air-raid Precautions and the Engineering Industry (Conference arranged by the Institutions of Electrical, Civil and Mechanical Engineers with the co-operation of the Ministry of Home Security), 673
Alga (Halophilic) in Mid-Cheshire, Occurrence of a (Burke, Frederick), 331
Algal Chemistry, Some Aspects of (Heilbron, Prof. I. M.), 398
Algebra, Intermediate (McArthur, Neil, and Keith, Alexander), *review*, 453
Algebraic Solid Geometry (Green, S. L.), *review*, 371
Alloys (Ferrous) and Foundry Materials, The Chemical Analysis of (Pigott, E. C.), *review*, 485
Alum, Lithium (Horan, H. A., and Duane, J. J.), 250
Amalgams (Dental), Excessive Expansion of (Schoonover, J. C.), 305
America (West Coast of Central), Crabs of the Genus Uca from the (Crane, Jocelyn), 145
American Association for the Advancement of Science, Prof. Arthur H. Compton elected president, 377; nineteenth 1,000 dollar prize awarded to Dr. Dugald E. S. Brown, Dr. Douglas A. Marsland and Dr. Frank H. Johnson, 377; (Geological Society of America and the), Geological Symposia held during the celebration of the fiftieth anniversary of the University of Chicago, 26, 156
American Association of Petroleum Geologists, Symposium on Possible Future Oil Provinces of the United States and Canada, *review*, 4
American Central Plains, Native Subsistence on the, 145
American Chemical Society, Dr. Per K. Frolich elected president for 1943, 216; report on technically trained chemists in the United States, 434
American Institute of the Aeronautical Sciences, John Jeffries award given to Major Harry G. Armstrong, 469
American Institute of Electrical Engineers, Edison Medal for 1941 awarded to Prof. J. B. Whitehead, 217; Alfred Nobel Prize for 1940–41 awarded to Robert F. Hays, jun., 438
American Medical Association, report on feeding factory workers in the United States, 434
American Philosophical Society, John Scott Medals and Premiums awarded to Major Edwin H. Armstrong, and Robert R. Williams, 243; Symposium on the United States Antarctic Expedition, 1939–41, 319; Research Grants, 694; Series of short-wave broadcasts, 728
American Society for Testing Materials, Card Index of X-ray Diffraction Data, 437
American Thought and Culture, Broadcasts on, 728
Amino Acids, and the Human Being (Gaunt, Wm. E.), 666; Physiology of the (van Slyke, Dr. Donald D.), 342; (Bacharach, A. L.), 473
p-Aminobenzoic Acid, Neutralization of Sulphonamide Inhibition of Yeast Growth by (Landy, Dr. Maurice, and Dicken, Dorothy M.), 244; Relative Acidity and Basicity of Sulphanilamide and (Albert, Dr. Adrien, and Goldacre, Dr. Reginald), 245
2-Aminofluorene as Growth Inhibitor for Bacteria and Rats (Bielschowsky, F., and Green, Prof. H. N.), 526, *erratum*, 607
Ammonia (Excretion of) by Blowfly Larvæ (Lennox, F. G.), 332
Amœbæ, Mitosis in (Taylor, Dr. Monica, and Hayes, Carmela), 501
Amphibian Pituitary, The (Hogben, Prof. Lancelot), 695

Amplifier (Direct-Current) in Industry (Gall, D. C.), 436
Analyse Ourselves ?, Can We, *review* by Dr. Millais Culpin, 713
Analysis, Adsorption of Metals of the Iron Group in (Austin, G. J.), 276
Analysis of Certain Foods, 641
Analysis of Foods (Lerrigo, A. F.), *review*, 151
Analysis of Modern Steels, *review*, 485
Analysis (Chemical) of Ferrous Alloys and Foundry Materials (Pigott, E. C.), *review*, 485
Analysis (Elementary Qualitative) for College Students (Reedy, Prof. J. H.), third edition, *review*, 486
Analysis (Elementary Qualitative), A New Scheme of (Mee, A. J.), *review*, 486
Analysis, Food (Woodman, Prof. A. G.), fourth edition, *review* by A. F. Lerrigo, 151
Analysis, Intermediate Quantitative (Welch, Dr. A. J. E.), *review*, 486
Analysis (Self-), A Practical Method of (Farrow, Dr. E. Pickworth), *review* by Dr. Millais Culpin, 713
Analytical Data of Soya Bean Meal and of Cereal Fillers (Illing, E. T., and Whittle, E. G.), 641
Analytical Foundations of Celestial Mechanics (Wintner, Aurel), *review* by Prof. H. C. Plummer, 534
Anastrepha (Genus), Fruitflies of the (Stone, Alan), 670
Ancestry of Captorhinomorph Reptiles (Westoll, Dr. T. S.), 667
Andes, Geophysical Institute of the, 354
Angiosperm Phylogeny, Floral Morphology and (Matthews, J. R.), 359
Anglo-American Co-operation in Scientific Research (Conant, President James B.), 10
Anglo-Czechoslovak Relations, History of (Kleiner, Dr. Kamil), 378
Animal Ecology, Predictive Method in (Maclagan, Dr. D. Stewart), 115
Animal Husbandry in India (Olver, Sir Arthur), 489
Animal Rations, Coffee Grounds in (Wilson, W. King), 361
Animal Welfare, Universities' Federation for, fifteenth annual report, 353
Animals as Food Converters (Halnan, E. T.), 318
Animals (Domestic), Carrots for (Woodman, H. E.), 190
Animals (Living), Regulation of Experiments on (Mitchell, Sir P. Chalmers), 699
Animals and Man (Rival Claims of) for Food (Wright, Dr. N. C.), 318
Animals and Plants, Rapid Determination of Water in (Lowndes, A. G.), 79
Anœstrus in Elephantulus, Acute Inhibition of the Corpus Luteum Excited by the Onset of (Horst, C. J. van der, and Gillman, Dr. Joseph), 329
Antarctic Expedition (United States), 1939–41, 319
Anthracotheriidæ in Ceylon (Deraniyagala, P. E. P.), 330
Anthropological Approach to the Study of Music (Angold, F. H.), 186
Antibodies, The Production of (Burnet, Dr. F. M.), *review* by Prof. A. A. Miles, 562
Ape-Man, *Paranthropus robustus*, The Hand of the (Broom, Dr. R.), 513
Apes (Why Men Behave Like) and Vice Versa (Hooton, Earnest Albert), *review* by Dr. S. Zuckerman, 340
Appeasement Before, During and After the War (Einzig, Paul), 481
Appointments Department of the Ministry of Labour and National Service, 496
Apprenticeship Scheme, Vacation, 107
'Aquadag' (Acheson, E. G.), 298
Arc, A Brilliant Atmospheric (Dufton, A. F.), 46
Architects, Royal Institute of British (Reconstruction Committee of the), Legislation affecting Town and Country Planning, 588
Argentine, Medical Advances in the (Houssay, Dr. B. A.), 437; Scientific Workers of the, 576
Army, Mechanical Engineers in the, 324
Arsenal of Democracy (Brown, A. J.), 522
Art, Meteorology in, 326
Art (Human Graphic), Origins of (Huxley, Prof. Julian S.), 637, 733; (Bowen, J. Leonard), 733
Art (Science and) at the Royal Academy, 1942 (Hopwood, Dr. A. T.), 603
Artefacts (Ground and Polished Prehistoric) from Ceylon (Deraniyagala, P.E.P.), 384
Arteries of the Forearm in Carnivores (Davis, D. Dwight), 414
Artichoke, Sweet Corn, Asparagus, Rhubarb and Seakale, Uncommon Diseases of (Green, D. E.), 641
Ascorbic Acid in Oranges (Lampitt, Dr. L. H., and Baker, L. C.), 271
Ascorbic Acid (Disappearance of the) in Raw Cabbage after Mincing or Chopping (Lampitt, Dr. L. H., Baker, Dr. L. C., and Parkinson, Dr. T. L.), 697
Ascorbic Acid (Effect of) on the Survival of Traumatized Animals (Ungar, Dr. Georges), 637
Asia, New Silver Firs from (Hillier, Edwin L.), 275
Asparagus, Rhubarb, Seakale, Artichoke and Sweet Corn, Uncommon Diseases of (Green, D. E.), 641
Aspergillus clavatus, Bactericidal Effects of (Wiesner, Dr. B. P.), 356
Assay (Biological) of Insecticidal Sprays (Parkin, Dr. E. A.), 720
Assay (Microbiological) of Riboflavin in Cereals (Barton-Wright, Dr. E.), 696
Astrographics, or First Steps in Navigation by the Stars (Debenham, Prof. Frank), *review* by Dr. H. Spencer Jones, 450
Astronomical Society, Royal, Jackson-Gwilt Medal and Gift awarded to Dr. R. L. Waterfield, 217
Athenæum, Elections to the, 75, 217, 327
Atlantic Charter, Mineral Resources and the (Division for the Social and International Relations of Science of the British Association, Conference on), 728
Atlantic Ocean (North), Earthquake between the Azores and Portugal on November 25, 1941, 165
Atmosphere, Microbiology of the, 387
Atmospheric Arc, A Brilliant (Dufton, A. F.), 46
Atmospheric Temperature, Solar Radiation and (Arctowski, Dr. H.), 276
Atomic Structure (Should an Outline of) be taught in the School Certificate Chemistry Course ? (Wellings, A. W., and James, Dr. E. J. F.), 459
Atomic Weights of Silver, Bromine and Potassium (McAlpine, R. K., and Bird, E. J.), 305
Atoms (New) for Old, *review* by Prof. James Kendall, 680
Attenuation, High-frequency (Noyes, H. B.), 415
XZ Aurigæ, an N-Type Variable (Alter, G. and Edwards, D. L.), 25
Australia, Production of Optical Glass in (Hartung, Prof. E. J.), 518; Search for Petroleum in (Demaine, C. S.), 303; (Milner, H. B.), 303
Australia (South), Modern Stone-Age Man in, 641
Australian Anthropological Association, 325
Australian National Research Council, hospitality in Australian laboratories, 17, 23
Australian Wind Tunnel, 388
Austrian Engineers, Chemists and Scientific Workers in Great Britain, formation of Association of, 577
Auto-correlation of Meteorological Time Series, The Problem of (Schumann, T. E. W., and Hofmeyer, W. L.), 414
Autolysis (Microbial Synthesis and) in the Digestive Tract of Herbivora (Baker, Frank), 582
Autonomy of Life, The Problem of the (Donnan, Prof. F. G.), *review*, 394; (Kapp, Prof. Reginald O.), 551; (Beadnell, Surgeon Rear-Admiral C. M.), 551; (Donnan, Prof. F. G.), 551

B.A.B. Fluorescent System of Lighting (Colloidal Research Laboratories, Ltd.), 106
Background to National Planning, 31
Bacteria and Rats, 2-Aminofluorene as Growth Inhibitor for (Bielschowsky, F., and Green, Prof. H. N.), 526, *erratum*, 607
Bacterial Metabolic Products (Toxic Effects of Certain) on Soil Protozoa (Singh, Dr. B. N.), 168
Bacterial Polysaccharides, Enzymatic Production of (Stacey, Dr. M.), 639

Bactericidal Effects of *Aspergillus clavatus* (Wiesner, Dr. D. P.), 356
Bacteriological Water-Sampler, A. (ZoBell, C. E.) 476
Balloon, Crystallization in an Inflated Rubber (Schallamach, Adolf), 112
Banana Research in Trinidad (Wardlaw, Prof. C. W.), 269
Barley, Respiration in (James, W. O., and Bunting, —.), 222
Barrage Balloon Cables, Aircraft Defence against, 73
Basicity (Relative Acidity and) of Sulphanilamide and *p*-Aminobenzoic Acid (Albert, Dr. Adrien, and Goldacre, Dr. Reginald), 245
Basis of Reconstruction, The (Bowie, Dr. J. A.), 337
Beaches (Pleistocene Raised) on the West Coast of Morocco (Breuil, Abbé H.), 77
Bearings, Economy of Tin in, 523
Bee Diseases (Liebefeld Research Institute), 222
Bee Keeping, Problems of, 222; in War-time (Butler, Dr. C. G.), 409
Bees, European Foul Brood of (Burri, Prof. R.), 222
Bees, Frow Remedy for Acarine Disease of (Peterka, V., and Svoboda, J.), 222
Beetles, Pine Shoot (Ossowski, Dr. Leon), 252
Beetles of the Family Lathridiidæ (Hinton, Dr. H. E.), 141
Behaviour, Chromatic (Hogben, Prof. L.), 735
Behring (Emil von) prize, founded by the University of Marburg, 665
Belgium and the War (Clark, Prof. G. N.), 607
Bengal, Aims and objects of eugenic researches in (Sarkar, S. S.), 382
3 : 4-Benzpyrene, Metabolic Products of (Berenblum, Dr. I., and Schoental, R.), 439
Bessemer Gold Medal of the Iron and Steel Institute for 1942 awarded to Eugene G. Grace, 75
Beyond the "Isms" (Stapledon, Olaf), *review* by F. S. Marvin, 593
Bibliography, of Pharmacology and Chemotherapy, 166; of Seismology, July–December, 1941 (Hodgson, Ernest A.), 665
Biogeographic Division of the Indo-Australian Archipelago (Scrivenor, J. B.), 556
Biological Assay of Insecticidal Sprays (Parkin, Dr. E. A.), 720
Biological Fact, Racial Theories and (Haldane, Prof. J. B. S.), 426
Biological Instruction and Training for Citizenship (Hogben, Prof. Lancelot), 354, 456
Biological Productivity of Lakes (Juday, C.), 24
Biological Research, Protozoa in (edited by Calkins, Gary N., and Summers, Francis M.), *review* by Clifford Dobell, 149
Biological Research in China, 353
Biological Sciences in the U.S.S.R. (Haldane, Prof. J. B. S.), 546
Biological Systems, Linkage of Physico-Chemical Processes in (Conway, Prof. Edward J.), 383, *erratum*, 438; (Donnan, Prof. F. G.), 383
Biologist, Physical Instruments for the (Bronk, Detler W.), 436
Biologists in War-time, 227
Biologists (Applied), Association of, symposium on Domestic Entomology, 295
Biology as a Social Science (Neville-Rolfe, Mrs. S.), 90; (Brimble, L. J. F.), 457
Biology and War (Kerr, Sir John Graham), 221
Biology War Committee, 234
Biology, Cine- (Durden, J. V., Field, Mary, and Smith, F. Percy), *review*, 155
Biology (Modern), The Influence of (Renouf, Prof. Louis), 515
Biology (Quantitative), Symposia on, Vol. 9, 242
Bio-Physics in the United States, 436
Biotin as a Possible Growth Factor for Insects (Fraenkel, Dr. G., and Blewell, M.), 301
Birds, British, *review* by Seton Gordon, 35; of Leicestershire, 74; of the Liverpool Area (Hardy, Eric), *review* by R. K. Perry, 287; of the Midlands, 378
Birds, In Search of Northern (Gordon, Seton), *review*, 371
Birds (Influx of Rare Winter) into Britain, 378
Black Lamb and Grey Falcon, the Record of a Journey through Yugoslavia in 1937 (West, Rebecca), *review* by Prof. J. L. Myres, 449
Blackening of Golgi Bodies by Osmium Tetroxide and Silver Nitrate (Weel, P. B. v., and Ries, E.), 52
Blindness, Prevention of, 665
Blood Cells (Red), Sedimentation of Washed (Whittington, R. B.), 305
Blood Groups (Surnames and), with a Note on a Probable Remarkable Difference between North and South Wales (Roberts, J. A. Fraser), 138
Blowfly Larvæ, Excretion of Ammonia by (Lennox, F. G.), 332
Board of Education scheme of State bursaries in science, 108
Bomb Damage, Cable Breakdowns due to (Beavis, E. A.), 435
Bone-marrow (Human) and Cancer, An Isotopic Shift of Potassium in (Lasnitzki, Dr. A., and Brewer, Dr. A. K.), 357
Book of Visions, A, *review* by Prof. R. M. Dawkins, 714
Books, Recent Scientific and Technical, Supp. ii, January 31; Supp. ii, February 28; Supp. ii, March 28; Supp. ii, April 25; Supp. ii, May 30; Supp. ii, June 27
Books for Damaged University Libraries, 434
Boron, Lower Oxides of (Ray, R. C., and Sinha, P. C.), 305
Bostik B. glazing compound, 136
Botanical Laboratory, Formulæ and Tables for the, *review*, 150
Botany of the Canadian Eastern Arctic, Part I: Pteridophyta and Spermatophyta (Polunin, Nicholas), *review* by A. J. Wilmott, 5
Bovine Cervical Mucus, Elasticity of (Blair, Dr. G. W. Scott, and others), 222
Bovine Contagious Abortion (Francis, F.), 663
Brashear, 'Uncle John', *review* by Dr. H. Spencer Jones, 283
Brassica and Raphanus, Self-incompatibility in Polyploid Forms of (Howard, Dr. W. H.), 302
Brazil, Leprosy in, 636
Bread, National (Staff of the Research Association of British Flour-Millers), 460
Bread, Wheatmeal Flour and, 323
Breakdown (Thermal) in Supertension Cables (Beavis, E. A.), 737
Breeding Sites (Natural) of *Drosophila obscura* (Gordon, Dr. Cecil), 499
Britain, Influx of Rare Winter Birds into, 378; Planning and Rebuilding in, 496
Britain, Replanning: being a Summarized Report of the Oxford Conference of the Town and Country Planning Association, 31
Britain Must Rebuild, a Pattern for Planning (Pick, Frank), 32
Britain's "New Order", a Plea for a Sane Post-War Employment Policy (Wyatt, T. W., and Jones, D. Caradog), 117
British Association, and the Social Sciences, 165; Conference on European Agriculture: Scientific Problems in Post-War Reconstruction, 189, 327; Conference on Science and World Order, 189
British Association (Division for the Social and International Relations of Science), Conference on Post-War Agricultural Reconstruction, 372; Conference on Raw Materials and Industrial Needs: Mineral Resources and Outlook, 576; Conference on Mineral Resources and the Atlantic Charter, 728
British Birds, *review* by Seton Gordon, 35
British Chemical Plant Manufacturers' Association, Official Directory for 1941, 217
British Electrical and Allied Industries Research Association twenth-first annual report, 215
British Empire, Drug Production in the (Ashby, Dr. Maurice), 225
British Federation of University Women, to collect books for damaged University Libraries, 434
British Pharmaceutical Codex, 1934, Supplement to, Part I: Monographs (New Monographs), *review*, 593
British Psychological Society, symposium on Social Stratification, 487
British Reconstruction Associations (P.E.P. Broadsheet), 521
British Restaurants, The Function of, 675
British Rheologists' Club, discussion on Classification of Rheological Properties, 197
British Scientists (Gregory, Sir Richard), *review* by J. G. Crowther, 8
British Social Hygiene Council, courses in biology for teachers, 192
British Thermal Unit, History of the (Powell, Dr. R. W.), 525; (Woledge, W.), 613

British Trust for Ornithology, Wood Pigeon Investigation, 191
British War Production, An Inquiry into, Part I: People in Production (Advertising Service Guild Report prepared by Mass-Observation), *review*, 711
Brittle Temperature of Rubber (Selker, M. L.), 645
Broadcasting, Technical Developments in (Bishop, H.), 269
Broadcasts, on American Thought and Culture, 728; on the Sub-visible Universe, 108
Bromine, Potassium and Silver, Atomic Weights of (McAlpine, R. K., and Bird, E. J.), 305
Bronze Age Implements in the Mortimer Museum, Hull (Sheppard, T.), 694
Brought Out in Evidence, an Autobiographical Summing-Up (Bowyer, William), *review* by Prof. W. G. de Burgh, 315
Bruce-Preller lecture for 1941 (Holland, Sir Thomas), 249
Bubble (Soap), Time of Collapse of a (Sibaiya, Dr. L.), 527
Building Industry, Reconstruction and the, 419; Training and Recruitment for the (Cole, G. D. H.), 419
Building and Civil Engineering Work, British Standards Institution codes of practice for, 578
Buildings, Heat Requirements of, 242
Burma, Game Preservation in, 29; Meteorology in, 379
Butterflies, a Handbook of the Butterflies of the United States (Macy, Prof. Ralph W., and Shepard, Prof. Harold H.), *review*, 8

CABBAGE (Disappearance of the Ascorbic Acid in Raw) after Mincing or Chopping (Lampitt, Dr. L. H., Baker, L. C., and Parkinson, Dr. T. L.), 697
Cabbage Caterpillars, Control of (Reid, W. J., jun., and collaborators), 414
Cable, New Exchange-Area (Firth, N. V.), 694
Cable Breakdowns due to Bomb Damage (Beavis, E. A.), 435
Cable Engineering (Melson, S. W.), 242
Cables, Electric, 242; Insulating Oils for (Beckinsale, S.), 703
Cables (High-voltage), Impulse Electric Strength of (Davis, R.), 360
Cables (Supertension), Thermal Breakdown in (Beavis, E. A.), 737
Calcium Nutrition of the Fœtus (Duckworth, Dr. John), 731
Calculating Machine (The Twin Marchant) and its Application to Survey Problems (Comrie, Dr. L. J.), *review*, 425
Calculation of Steric Hindrance (Evans, A. G., and Polanyi, Prof. M.), 608, 665
Calculus, Tensor, *review* by Prof. L. M. Milne-Thomson, 535
Calendar Reform, U.S. National Academy of Sciences and, 523
California, Earthquake at Santa Barbara on June 30, 1941, 299
Cambridge Evacuation Survey (edited by Isaacs, Susan), *review* by Dr. A. W. Wolters, 152
Camera Lucida for Transcribing Diagrams, Use of the (Dawes, Dr. Ben), 140
Canada, Food Investigations in, 27; Manufacture of Optical Glass in, 735; A Naturalist in (McCowan, Dan), *review* by Dr. A. E. Cameron, 154; Scientific and Industrial Research in, 80; Synthetic Rubber Production in, 327
Canadian Arctic Botany, *review* by A. J. Wilmott, 5
Canadian Natural History, *review* by Dr. A. E. Cameron, 154
Canal, The Projected Grand Contour (Pownall, J. F.), 467
Cancer, Pan-American League for the Control of, meeting at Buenos Aires, 136
Cancer (Human Bone-marrow and), An Isotopic Shift of Potassium in (Lasnitzki, Dr. A., and Brewer, Dr. A. K.), 357
Canet (Gustave) Memorial Lecture of the Junior Institution of Engineers on Scientific Research and Development in the Empire (Hill, Prof. A. V.), 653
Canteen Feeding (Clark, F. Le Gros, and Pirie, Dr. N. W.), 685
Cantor Lectures on X-Ray Technique in the Industrial Laboratory (Rooksby, H. P.), 597
Capacitance Bridge (An Improved) for Precision Measurements (Voelker, W. D.), 468
Carbon, A New Structure of (Lipson, Dr. H., and Stokes, A. R.), 328
Carbon Dioxide, Respiration and the Assimilation of, 29
Carbon Isotope (Heavy), in Plant Metabolism (Belkengren, R., Nier, A. O., and Burr, G. O.), 24
Carbonic Acid, Decomposition of (Roughton, F. J. W.), 305
Carbonization, Gaseous Products of (Bolton, K., Cullingworth, J. E., Ghosh, B. P., and Cobb, J. W.), 700
Carcinus maenas, Structure of the Branchiæ of (Smyth, J. D.), 472
Carnegie Corporation of New York, report for the year ended September 30, 1941, 190
Carnegie Institution of Washington, Year Book No. 40, 1940–1941, 557
Carnegie Trust for the Universities of Scotland, fortieth annual report of, 353
Carnegie United Kingdom Trust, twenty-eighth annual report of, 635
Carnivores, The Arteries of the Forearm in (Davis, D. Dwight), 414
β-Carotene (Absorption of Minimal Doses of), by Vitamin A-Deficient Rats (Ramasarma, G. B., and Hakim, D. N.), 611
Carrots for Domestic Animals (Woodman, H. E.), 190
Catalysis, Acid-Base (Bell, R. P.), *review* by Prof. M. Polanyi, 103
Catalysis Theory (Acid-Base), Decline and Revival of, *review* by Prof. M. Polanyi, 103
Catalytic Dimerization of Isobutene by Activated Copper Sulphide (Wassermann, Dr. A., and Weller, W. T.), 669
Caterpillars (Cabbage), Control of (Reid, W. J., jun., and collaborators), 414
Cattle, Artificial Insemination of, 438; Normal Rumen Microflora and Microfauna of (Baker, Frank), 220
Cattle Diseases, Control of, 663
Cecil Peace Prize, for 1941, awarded to the Hon. N. H. C. Bruce, 166; for 1942, 166
Celestial Mechanics, The Analytical Foundations of (Wintner, Aurel), *review* by Prof. H. C. Plummer, 534
Cell Division in Small and Large Cells (Sinnott, E. W.), 700
Cell (Dry) Manufacture, 381
Cell Walls, Dispersion of Cellulose Strands in (Frey-Wyssling, Prof. A.), 384; (Preston, Dr. R. D.), 580
Cells (Injured), Relation of Aeration to the Activity of Proliferation-Promoting Factors from (Loufbourow, Prof. John R., Webb, Dr. Alfred M., and Abramowitz, Rosaline K.), 272
Cellulose Acetate Yarn for Wire Insulation (Brobst, D. R.), 437
Cellulose Esters, Crystallinity in, 504
Cellulose Strands (Dispersion of) in Cell Walls (Frey-Wyssling, Prof. A.), 384; (Preston, Dr. R. D.), 580
Census (Demographic) of Rio de Janeiro, 523
Centenaries (Scientific) in 1942 (Smith, Eng. Capt. Edgar C.), 14
δ Cephei, Radial Velocity Curve of (Brück, H. A., and Green, H. E.), 333
Cereal Fillers (Soya Bean Meal and), Analytical Data of (Illing, E. T., and Whittle, E. G.), 641
Cereals, Microbiological Assay of Riboflavin in (Barton-Wright, Dr. E.), 696; Shoot Apex in Grasses and (Sharman, Dr. B. C.), 82
Cervical Mucus, Elasticity of Bovine (Blair, Dr. G. W. Scott, and others), 222
Ceylon, Anthracotheriidæ in (Deraniyagala, P. E. P.), 330; Ground and Polished Prehistoric Artefacts from (Deraniyagala, P. E. P.), 384; The Veddahs of (Hill, Prof. W. C. Osman), 113
Character, Form and, *review* by Dr. S. Zuckerman, 340
Chemical Aspects of Light (Bowen, E. J.), *review* by Dr. C. H. Bamford, 714
Chemical Aspects of Tuberculosis (Siebert, Dr. Florence B.), 443
Chemical Composition of Mitochondria (Baker, Dr. John R.), 611
Chemical Compounds, Inhibition of Growth by (Badger, G. M., *et al.*), 275
Chemical Constants (Physical and), Tables of (Kaye, Dr. G. W. C., and Laby, Prof. T. H.), ninth edition, review, 453
Chemical Engineering, The Applications of (edited by McCormack, Prof. Harry), *review* by Prof. H. E. Watson, 37; Soviet Developments in (Rose, H.), 546

Chemical Industry, Society of (Nutrition Panel of the Food Group) discussion on Green Leaves as a Source of Proteins and other Nutrients, 251; (Yorkshire section and the Food Group) discussion on Colours in Foods, 537
Chemical Kinetics (Mechanism and) of Organic Reactions in Liquid Systems (Hughes, Dr. E. D.), 126
Chemical Microscopy, Handbook of (Chamot, Prof. Émile Monnin, and Mason, Prof. Clyde Walter), Vol. 2: Chemical Methods and Inorganic Qualitative Analysis, second edition, *review*, 593
Chemical Plant (British) Manufacturers' Association, Official Directory for 1941, 217
Chemical Problems, Magnetism in Relation to (Mather, Dr. K. N.), *review* by Dr. W. Rogie Angus, 396
Chemical Reactions, Modern Theory of, *review* by Prof. M. Polanyi, 509
Chemical Society, eighth Hugo Müller lecture on Some Aspects of Algal Chemistry (Heilbron, Prof. I. M.), 398; first Sir Joseph J. Thomson Memorial Lecture to be given by Lord Rayleigh, 409
Chemical Species (La Notion d'espèce en chimie), (Timmermans, Prof. Jean), *review* by Prof. A. C. Egerton, 229
Chemical Warfare (Wachtel, Curt), *review*, 153
Chemist, Confessions of a, *review* by Dr. Harold King, 712
Chemistry (Algal), Some Aspects of (Heilbron, Prof. I. M.), 398
Chemistry (Analytical) of Industrial Poisons, Hazards and Solvents, The (Jacobs, Dr. Morris B.), *review*, 179
Chemistry (Clinical), Manual of (Reiner, Miriam), *review* by Dr. Joseph Geoghegan, 485
Chemistry (Elementary Physics and) for Students of Biology (Woodall, Dr. E. A., and Denne, E. C.), *review*, 425
Chemistry, Experimental Physical (Palmer, Dr. W. G.), *review*, 424
Chemistry (Organic), Modern Theories of (Watson, Dr. H. B.), second edition, *review* by Dr. J. Kenyon, 121
Chemistry (Physical) for Colleges (Millard, Prof. E. B.), fifth edition, *review*, 424
Chemistry, Practical Physical (Findlay, Prof. Alexander), seventh edition, *review*, 424
Chemistry, Quantum, 642
Chemistry in Clinical Medicine, *review* by Dr. Joseph Geoghegan, 485
Chemistry of Pterins (Hopkins, Sir Frederick Gowland), 359
Chemistry and Light, *review* by Dr. C. H. Bamford, 714
Chemists (Technically Trained) in the United States, 434
Chemotherapeutic Agents (Effect of Certain) on Experimental Eye Lesions produced by *Staphylococcus aureus* (Robson, Dr. J. M., and Scott, Dr. G. I.), 581
Chemotherapeutical Use of Halogenized Phenols as External Disinfectants (Zondek, Prof. Bernhard), 334
Chemotherapy, Bibliography of Pharmacology and, 166
Cheshire (Mid-), Occurrence of a Halophilic Alga in (Burke, Frederick), 331
Chicago, University of, Geological symposia held during the celebration of the fiftieth anniversary of the, 26, 156; symposium on Visual Mechanisms, 40; symposium on the Function of Air Currents, Temperature and Barometric Pressure in Disseminating Insects, Bacteria and Plant Diseases, 387
Child Psychology (edited by Skinner, Charles E., and Harriman, Philip Lawrence), *review* by T. Raymont, 204
Child-Study, Scientific, *review* by T. Raymont, 204
Chimiste, Souvenirs et travaux d'un (Pictet, Amé), *review* by Dr. Harold King, 712
China (Roxby, Prof. P. M.), 606; Biological Research in, 353; Medical Progress in (Woo, Dr. W. H.), 522; Reconstruction in (Kuo, Zing Yang), 42; Science and Engineering in, 693; Use of Soil Fertilizers in (Chang, N. F., and Richardson, Dr. H. L.), 410
China To-day, the Thirtieth Anniversary of the Chinese Republic, 1911–1941, 693
Christianity and the Mechanists (Greenwood, Dr. Osborne), 75
Chromatic Behaviour (Hogben, Prof. L.), 735
Chromosome Chemistry and Gene Action (Darlington, Dr. C. D.), 66
Chromosome Homologies in the Genus Drosophila (Sturtevant, A. H., and Novitski, F.), 141
"Chronica Botanica", Vol. 16, Nos. 17–18, 135
Cicada, Morphology of a (Evans, J. W.), 249
Cine-Biology (Durden, J. V., Field, Mary, and Smith, F. Percy), *review*, 155
Circuit-Breaker Failures, Insulating Oil in relation to (Cooper, W. Fordham), 703
Circuit-controlling Devices on Power Supply Systems (Marshall, C. W.), 673
Circulation by Experiment, Demonstration of the, 326
Citizenship, Biological Instruction and Training for (Hogben, Prof. Lancelot), 354, 456
Citizenship (Culture and), Education for, 447; Dymond, T. S.), 555
Civil Service, Future of the, 147
Civil Service (The Higher) of Great Britain (Dale, H. E.), 147
Civilization, Racialism and (Zollschan, Dr. I.), *review* by Prof. H. J. Fleure, 590
Civilization (European), Prehistory and (Hawkes, C. F. C.), 427
Class, Race, Nationality and (Torr, Miss Dora), 427
Class Consciousness and Class Unconsciousness (Harrisson, Tom), 487
Class Mind and Group Mind (Flugel, Prof. J. C.), 488
Classics, Science and the, 134
Classification of Rheological Properties, British Rheologists' Club discussion on, 197, 702
Climates (Pleistocene) in Kenya and Abyssinia (Kent, P. E.), 736
Cl. welchii Toxins, Lecithinase Activity of (Macfarlane, M. G., and Knight, B. C. J. G.), 222
Cl. welchii 'Toxins' Type A, Nomenclature of, 56
Clothing needs of scientific research workers and chemists (Plugge, Capt. L. F.), 469
Cloud and Rain, Electricity of (Chalmers, Dr. J. Alan), 659; (Simpson, Sir George), 659
Clough Memorial Research Fund, grants for 1942–43, 136
C/N Ratio of Soils, Influence of Temperature and *p*H on the (Dhar, Prof. N. R., and Pant, N. N.), 83
Coagulation (Rennet), The Second Phase of (Berridge, N. J.), 194
Coffee Grounds in Animal Rations (Wilson, W. King), 361
Colchicine and the Production of New Types of Forage Crops (Peto, F. H., and Young, G. A.), 641
Cold (Proteins Susceptible to) in Pathological Sera (Stein, L., and Wertheimer, Dr. E.), 528
Cold Storage of the Indian Potato (Karmarkar, Dr. D. V., and Joshi, B. M.), 199
Collapse of a Soap Bubble, Time of (Sibaiya, Dr. L.), 527
Collimator, A multi-purpose (Bracey, R. J.), 324
Colloidal Graphite Solutions, Uses of, 298
Colombia, Earthquake on May 23, 1942, 607
Colonial Development and Reconstruction, 365
Colonial Service appointments, 108, 217, 327, 438, 607, 694
Colorimetric Determination of Oxidation-Reduction Balance (British Drug Houses, Ltd.), third edition, 299
Colour Measurement (Smith, T., Guild, Dr. J., and Donaldson, R.), 76; (Harrison, Dr. V. G. W.), 76; (Perry, J. W.), 247, 553; (Guild, J.), 442
Colours in Foods (Society of Chemical Industry (Yorkshire section and the Food Group) discussion on), 537
Colours (Magnitudes and) of Northern Stars, 53
Comet 1941*c* (De Kock), Physical Features of (Stoy, R. H.), 144
Comet Grigg-Skjellerup, discovery by Kanna Sekituti, 636
Comet Positions by Cross-bar Micrometer (Hay, W. T.), 142
Commerce, Entomology of (Munro, Prof. J. W.), 352
Commercial Use of Scientific Data (English, Dr. S.), 497
Committee Decisions and Mathematical Statistics (Nicol, Dr. Hugh), 473
Community, Scientific Invention at the Service of the (Langdon-Davies, Capt. John), 298
Complex Variable, Functions of a (Phillips, E. G.), *review*, 181
Composition (Chemical) of Mitochondria (Baker, Dr. John R.), 611
Composts, Horticultural (Lawrence, W. J. C.), 438
Compression and Tension, 'Firmness' in, (Broome, Dr. D. C., and Bilmes, L.), 412
Concrete at Low Temperatures (Yates, J. C.), 360
Conditions in Factories, 116

Confessions of a Chemist, *review* by Dr. Harold King, 712
Contamination (Gas) Problem in the Engineering Industry, with special reference to Electrical Machinery (Martin, J. W.), 673
Continents, Evolution of (Holland, Sir Thomas), 249
Contour Canal, The Projected Grand (Pownall, J. F.), 467
Contours (Submarine) of the North Pacific (Betz, F., and Hess, H.), 359
Control (Quality) in Manufacture (Rissik, H.), 408; (Dudding, Bernard P.), 555
Control (Statistical) of Production (Darwin, Dr. C. G.), 573
Co-operation (Scientific) between Great Britain and the U.S.S.R., 297
Copper Sulphide (Activated), Catalytic Dimerization of Isobutene by (Wassermann, Dr. A., and Weller, W. T.), 669
Corona, Polarization of the (Allen, G. W.), 53; The Solar (Saha, Prof. M. N.), 524
Corpus Luteum (Acute Inhibition of the) Excited by the Onset of Anœstrus in the Elephantulus (Horst, C. J. van der, and Gillman, Dr. Joseph), 329
Corrosion, Environmental Factor in (Albano, V. J.), 223
Cosmic-Ray Showers, Penetrating (Jánossy, L.), 642
Cosmic Rays and Magnetic Storms (Duperier, Dr. A.), 579
Cosmical Origins of the Elements (Chandrasekhar, Prof. Subrahmanyan), 476
Cotton Seed Disinfection in War-time (Boughey, A. S.), 50
Country Planning (Town and), Legislation affecting (Report by the Reconstruction Committee of the Royal Institute of British Architects), 588
Cows (Pregnant and Non-pregnant), Rheological Properties of Secretions from the Cervix of (Blair, Dr. G. W. Scott, Cowie, A. T., and Coppen, F. M. V.), 609
Crabs of the Genus Uca from the West Coast of Central America (Crane, Jocelyn), 145
Crabs, Fiddler, 145
Croonian Lecture of the Royal Society on Chromatic Behaviour (Hogben, Prof. L.), 735
Crops (Forage), Colchicine and the Production of New Types of (Peto, F. H., and Young, A. G.), 641
Crops (Miscellaneous), Diseases of, 641
Cross-Incompatibility (Self- and) in Potatoes, Genetic Nature of (Pal, Dr. B. P., and Nath, Dr. Pushkar), 246
Crystal (Silicon Iron) in a Magnetic Field, Torque on a (Bozorth, R. M., and Williams, H. J.), 359
Crystal Analysis, A New Synthesis of X-Ray Data for (Yü, S. H.), 638
Crystal Dynamics of Rocksalt (Lonsdale, Dr. Kathleen), 698
Crystallization in an Inflated Rubber Balloon (Schallamach, Adolf), 112
Crystallinity in Cellulose Esters, 504
Crystallography (X-Ray), A New Method in (Orowan, Dr. E.), 355
Crystallography and Plant Viruses (Bawden, F. C.), 321; (Bernal, Prof. J. D., and Fankuchen, Dr. I.), 321
Crystals, Raman's Theory of Specific Heat of (George, Dr. W. H.), 540
Ctenodrilus in the Pacific, Occurrence of (Berkeley, C.), 248
Ctenophore from the Palestinian Coast (Haas, J.), 110
Culture in Norway, Suppression of, 407
Culture and Citizenship, Education for, 447; (Dymond, T. S.), 555
Cupric and Cuprous Compounds, Equilibrium between (Randles, J. E. B.), 333
Cuticle and Insect Ecology, Properties of (Uvarov, Dr. B. P.), 109; (Kalmus, Dr. H.), 109
Cyprus Earthquake, of January 20, 1941, Luminous Phenomenon accompanying the (Aziz, Abdulazim), 640
Cytochrome Component from Yeast, A New Soluble (Bach, S. J., Dixon, Dr. Malcolm, and Keilin, Prof. D.), 21
Cytoplasm of the Plant Cell (Guilliermond, Prof. Alexandre), translated by Dr. Lenette Rogers Atkinson, *review* by Dr. F. C. Steward, 484
Czech Medical Work in Britain, 73

DAMS, Uplift in (Leliavsky, Serge), 137
Darwin's "Formation of Vegetable Mould through the Action of Worms", A Postscript to (Keith, Sir Arthur), 716
Data, Engineering, *review*, 423
Data (Scientific), The Commercial Use of (English, Dr. S.), 497; in Glass Technology, 497
"Davitamon-Five" Vitamin Tablets, 299
Dear Joe: Letters from Bill Smith to Joseph Stalin (Robson, E. W. and M. M.), *review* by R. Brightman, 681
Decomposition of Carbonic Acid (Roughton, F. J. W.), 305
Defence, Forest Products and (Winslow, C. P.), 307
Defence of Industry, Design of Protective Structures and the (Baker, Prof. J. F.), 673
Deformation (A Type of Plastic) New in Metals (Orowan, Dr. E.), 643
Degeneration and Relict Adaptation (Huxley, Prof. Julian), 687
Dehydrogenase (Lactic) of Yeast (Bach, S. J., Dixon, Dr. Malcolm, and Zerfas, Dr. L. G.), 48
Democracy, The Arsenal of (Brown, A. J.), 522
Density of Population of the Pink Salmon (Davidson, F. A., and Vaughan, Elizabeth), 476
Dental Amalgams, Excessive Expansion of (Schoonover, J. C.), 305
Determination of Moisture (Vincent, R. S., and Simons, A.), 170
Determination (Growth and) in the Development of Drosophila (Waddington, Dr. C. H.), 264
Deuterium, Scattering of Neutrons in (Sundraachar, Prof. C. K., and Streib, Dr. J. F.), 51
Deuterium Compounds, Preparation of (Wilson, C. L., and Wylie, A. W.), 142
Development (Low-temperature Research and) in the Soviet Union (Ruhemann, Dr. M.), 546
Development (Scientific Research and) in the Empire (Hill, Prof. A. V.), 653
Development (Colonial) and Reconstruction, 365
Developments (Technical) in Broadcasting (Bishop, H.), 269
Diagrams, Preparation of Perspective (Hobson, Dr. G. D.), 209; Use of the Camera Lucida for Transcribing (Dawes, Dr. Ben), 140
Diamond, Extra Reflexions of X-Rays from (Lonsdale, Dr. Kathleen), 671
Dictionary of Scientific Terms as used in the Various Sciences (Beadnell, Surgeon Rear-Admiral C. M.), second edition, *review* by T. Raymont, 713
Dictionary (Statistical) of Terms and Symbols (Kurtz, Dr. Albert K., and Edgerton, Dr. Harold A.), *review* by M. G. Kendall, 371
Dietetics, Social Implications of (Mottram, Prof. V. H.), 269
Diffraction Data (X-Ray), Card Index of (American Society for Testing Materials), 437
Diffraction Patterns (Electron), Extra Spots in (Charlesby, A., and Wilman, H.), 411
Digestive Tract of Herbivora, Microbial Synthesis and Autolysis in the (Baker, Frank), 582
Dimerization (Catalytic) of Isobutene by Activated Copper Sulphide (Wassermann, Dr. A., and Weller, W. T.), 669
Dipole Moments, Solvent Effect and (Audsley, A., and Goss, F. R.), 276
Diptera, External Genitalia of the (Hardy, G. H.), 441
Dirac's Identity Connecting the Operators of Exchange and Spin, A Generalization of (Schrödinger, E.), 642
Direct-Current Amplifier in Industry (Gall, D. C.), 436
Discharge (Silent Electric), Activation of Nitrogen in the (Joshi, S. S., and Purushotham, A.), 250
Discharge Lamps, Electric, 75
Discharge Tube, A Reversible (Asundi, Prof. R. K., Singh, Nand Lal, and Singh, Jag Deo), 22; (Gaydon, Dr. A. G.), 112
Discomycete genus Rutstrœmia (White, W. Lawrence), 249
Disease and Race (Gorer, Dr. P. A.), 426
Diseases and War (Evans, Major Frederic), 606
Disinfectants, Chemotherapeutical Use of Halogenized Phenols as External (Zondek, Prof. Bernhard), 334
Disinfection (Cotton Seed) in War-time (Boughey, A. S.), 50
Dissipation Coefficient of Soft Materials, Psycho-Physical Significance of the (Blair, Dr. G. W. Scott, and Coppen, F. M. V.), 22
Dolerite at Hangnest, Petrological and Chemical Study of a 500-ft. Sill of (Walker, F., and Poldervaart, A.), 414

Dominate, The Impulse to (Harding, D. W.), *review* by H. G. Baynes, 203
Domination or Relationship, *review* by H. G. Baynes, 203
Driers and Drying, A Review of (Bennett, E. F.), *review*, 425
Drosophila, Chromosome Homologies in the Genus (Sturtevant, A. H., and Novitski, F.), 141; Growth and Determination in the Development of (Waddington, Dr. C. H.), 264; Meiosis in (Philip, Ursula), 527
Drosphila of Different Body Colour, Difference in Resistance to Toxic Substances of Mutants of (Kalmus, Dr. H., Martin. Dr. J. T., and Potter, C.), 110
Drosophila Culture, Polygenic Inheritance and the (Gordon, Dr. C., and Sang, J. H.), 610
Drosophila obscura, Natural Breeding Sites of (Gordon, Dr. Cecil), 499
Drosophila pseudo-obscura, Temperature and Sex Ratio in (Darlington, C. D., and Dobzhansky, Th.), 670
Drug Control in India, 417
Drug Production in the British Empire (Ashby, Dr. Maurice), 225
Drugs in France, Shortage of, 729
Drying (Driers and), A Review of (Bennett, E. J.), *review*, 425
Duddell Medal of the Physical Society, awarded to Dr. W. D. Coolidge, 521
Duddell Scholarship of the Institution of Electrical Engineers, 270
Duhem (Pierre), The Methodology of (Lowinger, Armand), *review* by Dr. H. Jeffreys, 564
Dyke Formation (Faulting and) The Dynamics of, with Applications to Britain (Anderson, Dr. E. M.), *review* by Prof. O. T. Jones,), 651
Dynamics (Crystal) of Rocksalt (Lonsdale, Dr. Kathleen), 698

EARTH and its Resources, The (Finch, Prof. Vernor C., Trewartha, Prof. Glenn T., and Shearer, M. H.), *review* by Prof. C. B. Fawcett, 232
Earthquake (Cyprus) of January 20, 1941, Luminous Phenomenon accompanying the (Aziz, Abdulazim), 640
Earthquake (Hindu Kush) of November 21, 1939 (Mukherjee, S. M., and Pillai, A. R.), 25
Earthquake Origins in the New Zealand Region (Hayes, R. C.), 146
Earthquakes, in Formosa on December 17, 1941, 20; in Turkey on December 17, 1941, 20; at Quetta on December 20, 1941, 20; in the Pacific Ocean south of Alaska on September 24, 1941, 165; in the Pacific Ocean north of Hawaii on September 25, 1941, 165; in the North Atlantic Ocean between the Azores and Portugal on November 25, 1941, 165; at Santa Barbara on June 30, 1941, 299; registered in New South Wales during July–September 1941, 380; registered at Kew during February 2–March 5, 1942, 409; in New Guinea on January 27, 1942, 434; in the Philippines on April 8, 1942, 435, 469; in New Zealand during 1940, 443; registered at Kew during March 8–April 7, 1942, 469; in the Pacific Ocean south of San José on March 1, 1942, 523; in the Pacific Ocean to the west of southern Chile on March 5, 1942, 523; in Ecuador on May 13–14, 1942, 578, 607, 694; registered at Kew on April 8, on April 13, and between April 15–May 5, 1942, 578; in Colombia on May 23, 1942, 607; registered in New Zealand during February 1942, 636; registered in Switzerland from October 1, 1941–January 31, 1942, 636; in Italy on November 10, 1941, and on January 2, 1942, 636; registered at Kew on May 14, 1942, 694
Earthquakes, The Cause of (Tillotson, Ernest), 539
Earth's Atmosphere, Downward Radiation of the (Narayanaswami, R., 279
Earwig in America, The European (Crumb, S. E., Eide, P. M., and Bonn, A. E.), 141
Echiuridæ, Sipunculidæ and Priapulidæ collected by the Ships of the Discovery Committee during the Years 1926 to 1937 (Stephen, A. C.), 57
"Ecology", Dr. Charles Olmsted appointed botanical editor of, 438
Economic Equilibrium, International, 311
Economic System, A Twentieth Century, 173
Economic and Social Research, National Institute of, 416
Economics in the U.S.S.R., *review* by R. Brightman, 681
Economics, Reconstruction and, 117
Economy (Soviet) and the War (Dobb, Maurice), *review* by R. Brightman, 681
Economy (War), The Contribution of Tropical Forests to (Desch, H. E.), 307
Ecuador, Earthquake on May 13-14, 1942, 578, 607, 694; Tuberculosis in (Higgins, Dr. Jorge), 498
Edison Medal of the American Institute of Electrical Engineers for 1941 awarded to Prof. J. B. Whitehead, 217
Education, The Place of Science in (de Ternant, Rev. Philip), 516
Education for Culture and Citizenship, 447 (Dymond, T. S.), 555
Education (Adult), Developments in (Yeaxlee, Dr. Basil A.), 504; as a Social Activity, 391
Education (Soviet School) Science in (King, Mrs. Beatrice), 547
Education, Technical (Orba, Alexander), 617; The Future of (Cull, H. J.), 615
Education and National Defence, Pamphlet No. 13: Hemisphere Solidarity, 106
Education and Nature, *review* by T. Raymont, 651
Education and Training of Engineets (Fleming, Dr. A. P. M.), 482
Educational Theory, Truth and Fallacy in (Hardie, Charles D.), *review* by T. Raymont, 651
Eighteenth Century, The French Civil Engineers of the (Hamilton, S. B.), 325
Eire, Health of, 136
Elasticity of Bovine Cervical Mucus (Blair, Dr. G. W. Scott, and others), 222
Electric Cables, 242
Electric Circuits, Transients in (Coulthard, Prof. W. B.), *review*, 287
Electric Discharge, The Efficient Production of Light by the (Francis, V. J.), 278
Electric Discharge (Silent), Activation of Nitrogen in the (Joshi, S. S., and Puroshotham, A.), 250
Electric Discharge Lamps, 75
Electric Heating of Premises (Gilchrist, W.), 408
Electric Power Stations (Carr, T. H.), vol. 2, *review*, 371
Electric Spark, The (Meek, J. M.), 360
Electric Strength (Impulse) of High-voltage Cables (Davis, R.), 360
Electrical (British) and Allied Industries Research Association, twenty-first annual report, 215; Investigation on transformer noise, 738
Electrical Circuits, Modern Devices Controlling, 673
Electrical Equipment, Manufacture and Testing of Oils and Oil-Rosin Saturants for use in (Thompson, A. W., and Wood-Mallock, J. C.), 703
Electrical Equipment for Farms, 381
Electrical Instruments, The Design and Performance of (Phillips, W.), 408
Electrical Space-heating Methods (Grierson, R.), 381
Electrical Machinery, Gas Contamination Problem in the Engineering Industry, with special reference to (Martin, J. W.), 673
Electrical Surges, Research on, *review* by Dr. T. E. Allibone, 621
Electrical Units, Names of (Kapp, Prof. Reginald O.), 111
Electrically Driven Excavators (Durand, P. H. R.), 664
Electricity, Intermediate (Hutchinson, Robert W.), *review*, 9
Electricity of Cloud and Rain (Chalmers, Dr. J. Alan), 659; Simpson, Sir George, 659
Electricity Board, Central (1933–1940), Surge Phenomena, Seven Years' Research for the, *review* by Dr. T. E. Allibone, 621
Electricity and Magnetism, A Laboratory Manual of (Loeb, Leonard B.), revised edition, *review*, 181
Electricity Supply, Air-raid Damage and, 173, 362, 435
Electrification in the Soviet Union (Vowles, H. P.), 546
Electromagnetic Mental Picture, The (Hatfield, Dr. H. Stafford), 248
Electromagnetism, The Story of (Bragg, Sir William), *review*, 425

Electron Beams, Space-Charge and (Petrie, D. P. R.), 671
Electron Diffraction Patterns, Extra Spots in (Charlesby, A., and Wilman, H.), 411
Electronics (Institute of Physics Conference on), 278
Electronics in Industry, 278
Electronics Group of the Institute of Physics, Formation of, 635; Sir Lawrence Bragg elected President of, 635
Elements, Cosmical Origins of the (Chandrasekhar, Prof. Subrahmanyan), 476
Elephantulus, Acute Inhibition of the Corpus Luteum Excited by the Onset of Anœstrus in (Horst, C. J. van der, and Gillman, Dr. Joseph), 329
Embryology of the Rhesus Monkey (*Macaca mulatta*), *review* by Dr. S. Zuckerman, 592
Empire, Scientific Research and Development in the (Hill, Prof. A. V.), 653
Empire Bond, The, 17
Emulsification and Absorption of Fats and Paraffins in the Intestine (Frazer, A. C., Stewart, H. C., and Schulman, Dr. J. H.), 167
"Endeavour", No. 1, 134
Endocrine Organs in Health and Disease, *review* by Dr. F. H. A. Marshall, 204
Endocrinology, Essentials of (Grollman, Dr. Arthur), *review* by Dr. F. H. A. Marshall, 204
Engineering (Chemical), Applications of (edited by McCormack, Prof. Harry), *review* by Prof. H. E. Watson, 37; Soviet Developments in (Rose H.), 546
Engineering (Civil) Work, Building and, British Standards Institution Codes of Practice for, 578
Engineering (Early Civil) in France, 325
Engineering (Electrical) Scholarships in (Institution of Electrical Engineers), 270
Engineering (Science and) in China, 693
Engineering Advisory and Scientific Advisory Committees, R. A. Butler to be chairman of the, 327
Engineering Data, *review*, 423
Engineering Design, *review*, 205
Engineering Industry, Air-raid Precautions and the (Conference arranged by the Institutions of Electrical, Civil and Mechanical Engineers with the co-operation of the Ministry of Home Security), 673; Gas Contamination Problem in the, with special reference to Electrical Machinery (Martin, J. W.), 673
Engineering Science, Relaxation Methods in (Southwell, Prof. R. V.), *review* by Prof. G. Temple, 123
Engineering (Illuminating) Society, annual general meeting on May 12, 576; R. O. Ackerley elected president, 576
Engineers, Education and Training of (Fleming, Dr. A. P. M.), 384
Engineers (The French Civil) of the Eighteenth Century (Hamilton, S. B.), 325
Engineers, Institution of Chemical, Osborne Reynolds Medal awarded to Dr. A. Parker, 409; Moulton Medal awarded to P. Parrish, 409; Junior Moulton Medal for 1941 not awarded, 409; William Macnab Medal awarded to E. W. Pates, 409
Engineers, Institution of Electrical, Faraday Medal awarded to Dr. Peter Kapitza; 241; Lt.-General A. G. L. McNaughton elected an honorary member, 243; Scholarships in Electrical Engineering, 270; Thirty-second Kelvin Lecture (Prof. Sydney Chapman), 277, *erratum*, 354; name of the Meter and Instrument Section altered to Measurements Section, 578; Awards of premiums, 578; (Wireless Section) Discussion on Post-War Planning in Radio Telecommunication, 614; discussion on Insulating Oils, 703; Report of the Council for the Year 1941–42, 704
Engineers, Institutions of Electrical, Civil and Mechanical, with the co-operation of the Ministry of Home Security, Conference on Air-raid Precautions and the Engineering Industry, 673
Engineers, Institution of Gas, E. V. Evans elected president for 1942–43, 729
Engineers, Institution of Heating and Ventilating, Recommendations for the Computation of Heat Requirements for Buildings, 242
Engineers, Institution of Mechanical, Colonel S. J. Thompson elected president of the, 243; James Watt International Medal awarded to A. G. M. Michell, 633
Engineers, Junior Institution of, ninth quadrennial Gustav Canet Memorial Lecture, 653
Engineers, Mathematics for (Dull, Raymond W.), second edition, *review*, 125
Engineers (Mechanical) in the Army, 324
Engineers, Physics for (Fleming, Sir Ambrose), *review*, 181
Engineer's Year-Book of Formulæ, etc. (Kempe, H. R., and Hanneford-Smith, W.), 48th annual issue, *review*, 423
England, Northern Fringe of the Palæolithic in (Gibson, Dr. H. N.), 111
English in the Science Course (Lyon, Hugh), 454
Entomological Society (Royal) of London, British Zoologist Prisoners of War in Europe, 248
Entomology of Commerce (Munro, Prof. J. W.), 352
Entomology (Domestic) in War-time (Busvine, Dr. J. R.), 295
Entomology (Economic) for South India, Handbook of (Ramakrishna Ayyar, Dr. T. V.), *review*, 9
Environment and Native Subsistence Economics in the Central Great Plains (Wedel, W. R.), 145
Environmental Factor in Corrosion (Albano, V. J.), 223
Enzymatic Production of Bacterial Polysaccharides (Stacey, Dr. M.), 639
Enzymatic Synthesis of Levan (Aschner, M., Avineri-Shapiro, S., and Hestrin, Dr. S.), 527
Epidemics in Haiti (Léon, Dr. Rulx), 379
Equations, Differential (Diwan, G. S., and Agashe, Prof. D. S.), *review*, 125
Equilibria, Exchange (Kingerley, R. W., and La Mer, V. K.), 415
Equilibrium between Cuprous and Cupric Compounds (Randles, J. E. B.), 333
Equisetites lyelli (Mantell), A Wealden Soil Bed with (Allen, P.), 474
Erysiphe, Mechanism of Germination of Conidia of (Brodie, Harold J., and Neufeld, C. C.), 332
Esson (William Beedie) Scholarship of the Institution of Electrical Engineers, 270
Esters (Cellulose), Crystallinity in, 504
Ethical and Political Remodelling of Society (Kenyon, Sir Frederic), 100
Ethics (Science and), a Hindu View (Gundappa, D. V.), 433
Eugenic Researches in Bengal, Aims and Objects of (Sarkar, S. S.), 382
Europe, Feeding Post-War (Bourne, Dr. Geoffrey), 182; *erratum*, 217
European Agriculture: Scientific Problems in Post-war Reconstruction, British Association Conference on, 189, 327
European Civilization, Prehistory and (Hawkes, C. F. C.), 427
European Foul Brood of Bees (Burri, Prof. R.), 222
Evacuation, Psychology of, *review* by Dr. A. W. Wolters, 152
Evacuation (Cambridge) Survey (edited by Isaacs, Susan), *review* by Dr. A. W. Wolters, 152
Evidence, Brought Out in, an Autobiographical Summing-Up (Bowyer, William), *review* by Prof. W. G. de Burgh, 315
Evolution of Continents (Holland, Sir Thomas), 249
Evolution in the Petroleum Industry (Kewley, James), 224
Ewing (James Alfred) Medal for 1941, awarded to Dr. F. W. Lanchester, 409
Excavators, Electrically Driven (Durand, P. H. R.), 664
Exchange Equilibria (Kingerley, R. W., and La Mer, V. K.), 415
Excitation of Nematocysts (Pantin, Dr. C. F. A.), 109
Excretion of Ammonia by Blowfly Larvæ (Lennox, F. G.), 332
Exeter, University College, Air-raid Damage, 636
Expansion (Excessive) of Dental Amalgams (Schoonover, J. C.), 305
Experiments, Chemical Engineering, *review* by Prof. H. E. Watson, 37
Experiments on Living Animals, Regulation of (Mitchell, Sir P. Chalmers), 699
Expiration, The 'Oxygen Trough' of (Mackay, Dr. Ian F. S.), 698
Explosives (Effect of High) on Structures (Bernal, Prof. J. D.), 673
Eye Lesions (Experimental) produced by *Staphylococcus aureus*, Effect of Certain Chemotherapeutic Agents on (Robson, Dr. J. M., and Scott, Dr. G. I.), 581

FACTORY Inspection, a Thirty-five Years' Retrospect (Wilson, Sir Duncan), 116
Fallacies of Racialism, *review* by Prof. H. J. Fleure, 590
Fallacy (Truth and) in Educational Theory (Hardie, Charles D.), *review* by T. Raymont, 651
Family Allowances (Jones, D. Caradog), 656
Fans, Sir Charles Parsons and Turbo-driven, 106
Far East and the War, 606
Faraday Medal of the Institution of Electrical Engineers, awarded to Dr. Peter Kapitza, 241
Farmer, The Indian, *review*, 510
Farmers (British), The Better Dissemination of Scientific Knowledge among (Parliamentary and Scientific Committee discussion on), 722
Farming as an Economic Industry, The Regeneration of (Hall, Sir A. Daniel), 208
Farming (Collective) in Russia and the Ukraine (Roberts, Dr. E. J.), 705; (Russell, Sir John), 705
Farms, Electrical Equipment for, 381
Fascism, Race and, 426
Fascism (The Scientific Attitude to), with particular reference to Racial Theories (Marx Memorial Library and Workers' School Symposium on), 327, 426
Fat (Pig Back Depot), Relative Firmness of (Bolton, W., and Baskett, R. G.), 670
Fats and Paraffins in the Intestine, Emulsification and Absorption of (Frazer, A. C., Stewart, H. C., and Schulman, Dr. J. H.), 167
Faulting and Dyke Formation (The Dynamics of), with Applications to Britain (Anderson, Dr. E. M.), *review* by Prof. O. T. Jones, 651
Fauna, Intertidal Sand, 670
Fauna of British India, including Ceylon and Burma, Mammalia, Vol. 2: Carnivora, Suborders *Æluroidea* (part) and Arctoidea, by R. I. Pocock, *review* by D. Seth-Smith, 122
Faunas (Upper Palæozoic) of North Sikkim (Muir-Wood, Helen M., and Oakley, Kenneth, P.), 172
Faxén-Waller Theory of Diffuse X-Ray Scattering (Jahn, H. A.), 701
Federal Union and Peace Aims, 434
Feeding, Canteen (Clark, F. Le Gros, and Pirie, Dr. N. W.), 685
Feeding (Collective) in War-time, Problems of (Nutrition Society Conference on), 469; 685
Feeding Factory Workers in the United States, 434
Feeding Post-War Europe (Bourne, Dr. Geoffrey), 182, *erratum*, 217
Fehling's Solution, Components of (Gaskin, J. G. N.), 250
Fertilizers (Soil) in China, Use of (Chang, N. F., and Richardson, Dr. H. L.), 410
Festivals, Primitive Scenes and (Sitwell, Sacheverell), *review* by Prof. R. M. Dawkins, 714
Fevers (Eruptive), Folk-lore of (Rolleston, Dr. J. D.), 335
Field Geology (Lahee, Dr. Frederic H.), fourth edition, *review*, 681
Field Museum of Natural History, volume in honour of Wilfred Hudson Osgood, 414
Fighting for What? (Orr, Sir John), *review* by Sir Richard Gregory, 678
Film (London Scientific) Society, 617
Films (Surface) of Lupane Derivatives (Bilham, P., Jones, E. R. H., and Meakins, R. J.), 415
Filters, Piezo-Electro Crystal (Benson, J. E.), 20
Fireflies, *review* by Sir D'Arcy W. Thompson, 258
'Firmness' in Compression and Tension (Broome, Dr. D. C., and Bilmes, L.), 412
Firs (New Silver) from Asia (Hillier, Edwin L.), 275
Fish, Study of a Deepwater, 700
Fish (Production of Freshwater) for Food (Macan, Dr. T. T., Mortimer, Dr. C. H., and Worthington, Dr. E. B.), 435
Fish Larva (The Tail of a) as Respiratory Organ (Sawaya, Prof. Paulo), 169
Fisheries, Irish, 30; Irish Sea and Inland (Report of the *Minister of Agriculture, Eire, for* 1940), 605
Fishes, Indian, 670; from the Philippines (Fowler, Henry W.), 700
Fishes, (Indian) and Mosquito Control, 644
Fitness for Military Service in the United States, 388
Flight, The Birth of (Cook, Hartley Kemball), *review* by Capt. J. L. Pritchard, 231
Flocculi (Hydrogen), Movements of, 642
Flocculi (Sunspots and Quasi-eruptive), Surges near (Ellison, M.A.), 642
Flooding (Rainfall) and Health (Graham, D. C.), 435
Floods (Hurricane) of September 1938 in New England (Brooks, Dr. C. E. P.), 556
Flora (A Late-Glacial) in Co. Monaghan, Ireland (Mitchell, G. F.), 502
Floral Morphology and Angiosperm Phylogeny (Matthews, J. R.), 359
Florida (Straits of), Oceanographic Observations across the (Montgomery, R. B.), 476
Flour-Millers, Research Association of British, report on the Storage of National Wheatmeal, 635
Flour and Bread, Wheatmeal, 323
Flow of Liquids in the Critical Region (Nissan, Dr. Alfred H.), 501
Flow of Liquids and Gases, Measurement of the (Ower, E.), 333
Flow (Steady), of a Viscous Fluid through a Leaky Tube, (Turton, F. J.), 53
Fluorescence of Methylcholanthrene (Hieger, Dr. I.), 300
Fluorescence of Polycyclic Hydrocarbons, Reversible Quenching by Oxygen of the (Weil-Malherbe, Dr. H., and Weiss, Dr. Joseph), 471, 612; (Bowen, E. J.), 528
Fluorescent Light Sources (Aldington, J. N.), 466
Fluorescent Lighting (Davies, L. J., Ruff, H. R., and Scott, W. J.), 577
Fluorescent Lipoidal Spectra of Human Tissue (Penn, Dr. H. S.), 193
Fluorescent System (B.A.B.) of Lighting (Colloidal Research Laboratories, Ltd.), 106
Fœtus, Calcium Nutrition of the (Duckworth, Dr. John), 731
Fœtus (Sex of the), Excretion of Ketosteroids in Human Pregnancy Urine in Relation to the (Burrows, Dr. Harold, MacLeod, Douglas H., and Warren, F. Ll.), 300
Folk-lore, of Eruptive Fevers (Rolleston, Dr. J. D.), 335; of Venereal Disease (Rolleston, Dr. J. D.), 705
Food, Production of Freshwater Fish for (Macan, Dr. T. T., Mortimer, Dr. C. H., and Worthington, Dr. E. B.), 435
Food for Livestock, Seaweed as a (Beharrell, J.), 306
Food Analysis (Woodman, Prof. A. G.), fourth edition, *review* by A. F. Lerrigo, 151
Food Converters, Animals as (Halnan, E. T.), 318
Food Investigation, Index to the Literature of, Vol. 13, No. 2, September 1941, 382
Food Investigations in Canada, 27
Food Policy, A Scientific, 309; (The Agricultural Implications of) based on Nutritional Needs (Orr, Sir John), 318
Food Production and Distribution in relation to Nutritional Needs (Nutrition Society Conference on), 192, 318
Food Production and Nutrition (Pirie, N. W.), 318
Food and Agriculture, 208
Food and Nutritional Needs, 192
Foods, Analysis of, *review* by A. F. Lerrigo, 151
Foods, Analysis of Certain, 641
Foods, Colours in (Society of Chemical Industry (Yorkshire Section and the Food Group) discussion on), 537
Foot-and-Mouth Disease, Starling Movements and the Spread of (Bullough, Dr. W. S.), 683
Forage Crops (New Types of), Colchicine and the Production of (Peto, F. H., and Young, G. A.), 641
Fordham University, degree of doctor of science awarded to Capt. N. H. Heck, 166
Foreign Men of Science in Great Britain, Association of Scientific Workers Committee to Help, 498
Forensic Science, *review* by Dr. J. Davidson, 536
Forest Administration in Malaya, including Brunei, for the Year 1940, Annual Report on (Watson, J. G.), 307
Forest Products and Defence (Winslow, C. P.), 307
Forest Products Research Laboratory, Handbook of Home Grown Timbers, third edition, 241
Forestry, in Malaya, 307; (West African) during 1940, 46
Forests, of India, 19; of New Zealand, 672; The Contribution of Tropical, to War Economy (Desch, H. E.), 307

Form and Character, *review* by Dr. S. Zuckerman, 340
Formosa, Earthquake of December 17, 1941, 20
Formulæ, Plant Science (McLean, Prof. R. C., and Cook, Dr. W. R. Ivimey), *review*, 150
Formulæ and Tables for the Botanical Laboratory, *review*, 150
Fossils (Permian) from the Eastern Himalaya (Wager, Dr. L. R.), 172
Foundations of the New World Order (Orr, Sir John), 401
Foundations (Analytical) of Celestial Mechanics (Wintner, Aurel), *review* by Prof. H. C. Plummer, 534
Foundry Materials (Ferrous Alloys and), The Chemical Analysis of (Pigott, E. C.), *review*, 485
Fourier Series and some Applications, *review*, 259
Fourier Series and Boundary Value Problems (Churchill, Prof. Ruel V.), *review*, 259
Fowl, Linkage Studies in the (Hutt, F. B.), 276
France, Shortage of Drugs in, 729
France (Napoleonic), Vaccination in (Dunbar, Dr. Robert C.), 379
Franklin Institute, *Journal* of the, December 1941, 243
Freedom, Science as a Force of (Lal, G. B.), 268
French Civil Engineers of the Eighteenth Century (Hamilton, S. B.), 325
Frenchman's View of Prehistory, A, *review* by M. C. Burkitt, 232
Frequencies (Ultra-High), Input Impedances of Vacuum Thermojunctions at (Rogers, D., and Williams, Gordon), 668
Frequency Comparisons, High-precision (Meacham, L. A.), 642
Freud (the Doctrine of), Psychoanalytical Method and (Dalbiez, Dr. Roland), *review* by Dr. John Cohen, 563
Friction, Mechanism of Kinetic (Bristow, J. R.), 169
Frow Remedy for Acarine Disease of Bees (Peterka, V., and Svoboda, J.), 222
Fruitflies of the Genus Anastrepha (Stone, Alan), 670
Fuel, Institute of, Melchett Medal for 1942 awarded to Dr. Arno Carl Fieldner, 523; William Morrish Selvey to continue as president, 694
Fuel Research, Development of (Smith, Dr. E. W.), 466
Functions of a Complex Variable, with Applications (Phillips, E. G.), *review*, 181
Fungi, Heterothallism and Reproduction in (Madge, Dr. Margaret A. P., and Blackwall, Elizabeth), 440; Heterothally as an Outbreeding Mechanism in (Mather, Dr. K.), 54
Fuse (H.R.C. Cartridge), A High-Voltage (Dannenberg, K., and John, W. J.), 474

GALACTIC Absorption and Apparent Distribution of Spectral Types (Alter, George), 360
Galileo Galilei, 1564–1642 (Plummer, Prof. H. C.), 206
Game Preservation in Burma, 29
Ganges (Lower) and its Courses, Antiquity of the (Bhattasali, N. K.), 468
Garden, The Message of the, *review* by Sir Frederick Keeble, 36
Gardiner Chair of Chemistry at Glasgow, Prof. T. S. Patterson retiring from, 407; Dr. J. Monteath Robertson appointed to, 407
Gas (Natural), A Liquefaction Plant for, 635
Gas Contamination Problem in the Engineering Industry, with special reference to Electrical Machinery (Martin, J. W.), 673
Gas Research Board, Second Report of the, 529; thirty-second report of the Refractory Materials Joint Committee, 529
Gaseous Products of Carbonization (Bolton, K., Cullingworth, J. E., Ghosh, B. P., and Cobb, J. W.), 700
Gases and Liquids, Measurement of the Flow of (Ower, E.), 333
Gear (Protective) on Power Supply Systems (Casson, W., and Birch, F. H.), 165
Geese (Wild), Mainly on, *review* by Seton Gordon, 564
Gene Action, Chromosome Chemistry and (Darlington, Dr. C. D.), 66
Genes, Viruses and Proteins, 242
Genetic Nature of Self- and Cross-Incompatibility in Potatoes (Pal, Dr. B. P., and Nath, Dr. Pushkar), 246
Genetics, New Paths in (Haldane, Prof. J. B. S.), *review* by Dr. C. D. Darlington, 317
Genetics Controversy in the U.S.S.R. (Fyfe, J. L.), 547
Genetics (Physiological) of Neurospora (Beadle, G. W., and Tatum, E. L.), 249
Genetics and the Origin of Species (Dobzhansky, Prof. Theodosius), second edition, *review* by Dr. K. Mather, 152
Genetics and Plant Breeding, Indian Journal of, volume for 1941, 325
Genetics and the Russian Controversy (Mather, Dr. K.), 427
Genetics of Speciation *review* by Dr. K. Mather, 152
Genitalia (External) of the Diptera (Hardy, G. H.), 441
Geography (Historical)—Then and Now, *review* by Dr. J. N. L. Baker, 103
Geography, Physical, *review* by Prof. C. B. Fawcett, 232
Geography and World Power (Fairgrieve, James), eighth edition, *review* by Dr. J. N. L. Baker, 103
Geological Society of London, Awards of the, 135; Wollaston Medal awarded to Prof. R. A. Daly, 164; First Publication of the, 377, (Eyles, Joan M.), 442, (Hawkes, Dr. L.), 555; joint meeting with the Institute of Physics (London and Home Counties' Branch) on Geophysical Methods in Geology, 690
Geological Society of America and the American Association for the Advancement of Science, Geological symposia held during the celebration of the fiftieth anniversary of the University of Chicago, 26, 156
Geological Text-Books, review, 681
Geologists in War-time, 282 (Phillips, Dr. F. Coles), 386
Geologists (Geology and) in the National War Effort (Read, Prof. H. H.), 39
Geology, Aspects of Modern (Bastin, Prof. Edson S.), 26; Field (Lahee, Dr. Frederic H.), fourth edition, *review*, 681; Geophysical Methods in, 690; Introduction to (Branson, Prof. E. B., and Tarr, Dr. W. A.), second edition, *review*, 681; of Libya (Sandford, K. S.), 389; in Soviet Economy (Henry, Dr. N. F. M.), 546; Text-Book of (Lake and Rastall's), fifth edition, *review*, 681; of the Weald, 474
Geology and Geologists in the National War Effort (Read, Prof. H. H.), 39
Geomagnetism (Chapman, Prof. Sydney, and Bartels, Prof. Julius), review by Sir Edward Appleton, 177; Progress of, *review* by Sir Edward Appleton, 177
Geometry, Algebraic Solid (Green, S. L.), *review*, 371; An Introduction to Differential, with Use of the Tensor Calculus (Eisenhart, Prof. Luther Pfahler), *review* by Prof. L. M. Milne-Thomson, 535; The Foundations of (Robinson, Prof. Gilbert de B.), *review*, 125
Geophysical Institute of the Andes, 354
Geophysical Methods in Geology, 690
Gephyrea, Recent Work on the, 57
German Academy of Natural Sciences at Halle, Prof. Emil Abderhalden appointed president for another ten years, 409
German Men of Science, Two Eminent, 727
German Romanticism, Natural Science in (Aesch, Alexander Gode-von), review by Prof. A. Wolf, 104
Germination (Seed), Linnean Society discussion on, 658
Glacial (A Late-) Flora in Co. Monaghan, Ireland (Mitchell, G. F.), 502
Glaciation and Submarine Valleys (Daly, Prof. Reginald A.), 156
Glasgow, University of, Gardiner Chair of Chemistry at, Prof. T. S. Patterson retiring from, 407; Dr. J. Monteath Robertson appointed to, 407
Glass (Optical), Some Problems relating to (Hampton, Dr. W. M.), 324; in Australia, Production of (Hartung, Prof. E. J.), 518; in Canada, Manufacture of, 735
Glass Technology, Scientific Data in, 497
Glass-house Repair, Rapid, 136
Glycerine (A Substitute for) as a Mounting Medium (Harris, Prof. T. M.), 554
Glycogen Phosphorylation (Decrease in) in Muscles *in vitro* after Adrenalectomy and Restoration with Desoxycorticosterone (Verzár, Prof. F., and Montigel, C.), 49

Goethe Medal for Art and Science, awarded to Prof. Erwin Payr, 108; awarded to Prof. Adolf Windaus, 438
Gold Coast Timbers, 522
Golf Courses during War-time, 326
Golgi Bodies (Blackening of) by Osmium Tetroxide and Silver Nitrate (Weel, P. B. v., and Ries, E.), 52
Gonadotropin (Chorionic) on the Pouch of the Marsupial *Trichosurus vulpecula*, Effect of (Bollinger, Dr. A.), 440
Government, A New Form of, 105
Government Plans for Reconstruction, 298
Granophyre, Metasomatic Origin of, 414
Graphite (Colloidal) Solutions, Uses of, 298
Grasses, Common Indian (Sharman, Dr. B. C.), 199
Grasses (Common) of the United Provinces (Bor. N. L.), 199
Grasses and Cereals, Shoot Apex in (Sharman, Dr. B. C.), 82
Grasshopper, Inheritance in the (Creighton, M., and Robertson, W. R. B.), 222; A Trisomic (Callon, H. G.), 24
Grassland Improvement Station, Dodwell (Ministry of Agriculture), Sir George Stapledon appointed director, 549
Grassland Research in Great Britain, 549
Gravimetric Micro-determination of Magnesium (Holt, P. F.), 642
Gray (Thomas) Memorial Trust Prize of the Royal Society of Arts, awarded to T. E. Metcalfe, 270
Great Britain, Austrian Science Workers in, 577; Grassland Research in, 549; Meteorological Research in, 544; Replanning, 587; and the United States, 17; Scientific Co-operation between, and the U.S.S.R., 297
Green Enchantment (Clarkson, Rosetta E.), *review* by Sir Frederick Keeble, 36
Green Line Source, A Remarkable (Kaplan, Prof. Joseph), 273
Grey Falcon (Black Lamb and), the Record of a Journey through Yugoslavia in 1937 (West, Rebecca), *review* by Prof. J. L. Myres, 449
Grigg-Skjellerup Comet, discovery by Kanna Sekituti, 636
Group Mind, Class Mind and (Flugel, Prof. J. C.), 488
Growth (Inhibition of) by Chemical Compounds (Badger, G. M., *et al.*), 275
Growth Inhibitor (2-Aminofluorene as) for Bacteria and Rats (Bielschowsky., F., and Green, Prof. H. N.), 526, *erratum*, 607
Growth and Determination in the Development of *Drosophila* (Waddington, Dr. C. H.), 264
Growth (Rate of) and Timber Quality (Johnson, L. P. V.), 332
Growth Factor for Insects, Biotin as a Possible (Fraenkel, Dr. G., and Blewett, M.), 301
Guthrie Lecture of the Physical Society, Sir Edward Appleton to deliver, 299

HAEMOGLOBIN, X-Ray Analysis of (Perutz, M. F.), 491
Hæmophilia-like Conditions in Pigs (Bogart, R., and Muhrer, M. E.), 641
Haiti, Epidemics in (Léon, Dr. Rulx), 379
Halley, Edmond, 1656–1742 (Jones, Dr. H. Spencer), 69; as Physical Geographer and the Story of his Charts (Chapman, Prof. S.), 56
Halley's Work as a Geographer (Baker, Dr. J. N. L.), 56
Halophilic Alga (Occurrence of a) in Mid-Cheshire (Burke, Frederick), 331
Hand in Healing, a Study in Greek Medicine from Hippocrates to Ramazzini (Farrington, Prof. B.), 529
Handbook of British Birds, Vol. 5 (Terns to Game-Birds, Additions and Corrections, Systematic List and Indices), (Witherby, H. F., editor, Jourdain, Rev. F. C. R., Ticehurst, Norman F., and Tucker, Bernard W.), *review* by Seton Gordon, 35
Hannah Dairy Research Institute, twelfth annual report of, 298
Harrison Memorial Prize for 1941 awarded to Dr. Henry Norman Rydon, 20
Harveyan Circulation by Experimental Tests, The Significance of the Demonstration of the (Bayon, H. P.), 326
Hate, Psychology of (Fromm, Dr. Erich), 728
Hazards (The Analytical Chemistry of Industrial Poisons), and Solvents (Jacobs, Dr. Morris B.), *review*, 179
Healing, The Hand in, a Study in Greek Medicine from Hippocrates to Ramazzini (Farrington, Prof. B.), 529
Health, of Eire, 136; of Palestine, 19; of Scotland, 74; of Tanganyika, 107; of the United States Army, 664
Health Contrasts in the United States, 664
Health Services and Population Problems, 707
Health, Rainfall Flooding and (Graham, D. C.), 435
Heart (Marsupial), Age Changes in Size of Muscle Fibres of the (Davies, Prof. Francis, and Francis, Dr. Eric T. B.), 410
Heat Requirements of Buildings, 242
Heat Transfer, Recent Progress in (Lander, Prof. C. H.), 723
Heating (Electric) of Premises (Gilchrist, W.), 408
Hebrew University, Jerusalem, 354
Hemisphere Solidarity (Education and National Defence, Pamphlet No. 13), 106
Heparin (MacIntosh, F. C.), 24
Herbivora, Microbial Synthesis and Autolysis in the Digestive Tract of (Baker, Frank), 582
Herbs for Daily Use in Home Medicine and Cookery (Quelch, Mary Thorne), *review*, 8
Heterothallism and Reproduction in Fungi (Madge, Dr. Margaret A. P., and Blackwell, Elizabeth), 440
Heterothally as an Outbreeding Mechanism in Fungi (Mather, Dr. K.), 54
Hexamethoxybenzene (Robinson, Sir Robert, and Vasey, C.), 52; (Baker, W.), 52
High Explosives (Effect of) on Structures (Bernal, Prof. J. D.), 673
High-frequency Attenuation (Noyes, H. B.), 415
High-voltage H.R.C. Cartridge Fuse (Dannenberg, K., and John, W. J.), 474
High-voltage Porcelain Insulators (Forrest, J. S.), 276
Hilger Vitameter A., A Modified (Taylor, R. J.), 474
Hill Sheep Farming, 108
Hilsa in Bengal Waters, Life-history and Wanderings of (Hora, Dr. Sunder Lal), 670
Himalaya, Peruvian Fossils from the Eastern (Wager, Dr. L. R.), 172
Hindu Kush Earthquake of November 21, 1939 (Mukherjee, S. M., and Pillai, A. R.), 25
Hippocratic Medicine, its Spirit and Method (Heidel, William Arthur), *review* by Dr. W. H. S. Jones, 422
Hirudinaria, the Indian Cattle Leech (Bhatia, Dr. M. L.), 437
Hobbes (Thomas), Modern Science and (Bell, A. E.), 688
Home Guard, Scientific Help for the (Langdon-Davies, Capt. John), 79
Homo sapiens, The Outlook for (Wells, H. G.), *review* by Rev. J. C. Hardwick, 316
Honours, New Year, 45; King's Birthday, 692
Hormonal Increase of Resistance and its Mechanism (Agduhr, Prof. Erik), 171
Horticultural Abstracts, Index to first ten volumes (Akenhead, D.), 19
Horticultural Composts (Lawrence, W. J. C.), 438
Horticultural Research, An Index to, 19
Hospitality in Australia for Scientific Workers (Carne, Dr. L. H. R.), 17, 23
H.R.C. Cartridge Fuse, A High-Voltage (Dannenberg, K., and John, W. J.), 474
Hull and at Plymouth, Nitzschia Cultures at (Wilson, D. P., and Lucas, C. E.), 331
Human Being, Amino-Acids and the (Gaunt, Wm. E.), 666
Human Biology, Summer School in, 192
Human Child, Wolf Child and (Gesell, Dr. Arnold), *review*, 181
Human Graphic Art, Origins of (Huxley, Prof. Julian S.), 637, 733; (Bowen, J. Leonard), 733
Human Prospects, Science and (Blackwelder, Prof. Eliot), *review* by F. S. Marvin, 623
Human Serum, Behaviour of Lipoids in (McFarlane, Dr. Arthur S.), 439
Human Tissue, Fluorescent Lipoidal Spectra of (Penn, Dr. H. S.), 193
Hurricane Floods of September 1938 in New England (Brooks, Dr. C. E. P.), 556
Husbandry (Animal) in India (Olver, Sir Arthur), 489
Hydrocarbons (Oxidation of) at Low Temperatures (George, P., Rideal, Prof. E. K., and Robertson, A.), 601

Hydrocarbons (Polycyclic), Reversible Quenching by Oxygen of the Fluorescence of (Weil-Malherbe, Dr. H., and Weiss, Dr. Joseph), 471, 612; (Bowen, E. J.), 528
Hydrogen Bonds Involving the Sulphur Atom (Heafield, T. G., Hopkins, G., and Hunter, Dr. L.), 218
Hydrogen Flocculi, Movements of, 642
Hydrogen Lines (Profiles of) in Two Class B Stars (Douglas, A. Vibert, and West, D. C.), 671
Hygiene, National Institute of, founded in Paris, 636
Hypotheses Non Fingo (Bell, A. E.), 238

IGNITRONS (Thyratrons and), The Control Characteristics of (Knight, H. de B.), 278
Images (Optical) formed by Conical Refraction (Raman, Sir C. V., and Nedungadi, T. M. K.), 552
Immunology, Speculations in, *review* by Prof. A. A. Miles, 562
Impact of Inventions on People (Jones, D. Caradog), *review*, 63
Impact of the Physical Sciences on Society (Crowther, Prof. J. A.), 96
Impedances (Input) of Vacuum Thermojunctions at Ultra-High Frequencies (Rogers, D., and Williams, Gordon), 668
Imperial College Union, Vacation Apprenticeship Scheme of the, 107
Imperial Forestry Institute, seventeenth annual report, for 1940–41, 523
Implements (An Unrecorded Method of Manufacturing Wooden) by Simple Stone Tools (Mountford, C. P.), 641
Impulse Voltage Measurements (Bowdler, G. W.), 701
Incomes in Rhodesia (Shaul, J. R. H.), 275
Incompatibility (Self- and Cross-) in Potatoes, Genetic Nature of (Pal, Dr. B. P., and Nath, Dr. Pushkar), 246
India, Agricultural Meteorology in, 216; Animal Husbandry in (Olver, Sir Arthur), 489; Breakdown of the negotiations conducted by Sir Stafford Cripps, 433; Mr. Churchill's announcement of March 11, 1942, on, 323; Drug Control in, 417; Eugenics in, 382; The Forests of, 19; Mammals of, *review* by D. Seth-Smith, 122; Half a Century of Population Trends in (Geddes, A.), 304; The Potato in (Kidd, Dr. Franklin), 199; Public Health in, 191
India (British), The Fauna of, including Ceylon and Burma, Mammalia, Vol. 2: Carnivora, Suborders Æluroidea (part) and Arctoidea (Pocock, R. I.), *review* by D. Seth-Smith, 122
Indian Farmer, The, *review*, 510
Indian Fishes, 670; and Mosquito Control, 644
Indian Grasses, Common (Sharman, Dr. B. C.), 199
Indian Home-grown Timbers, Utilization of, 279
Indian Journal of Genetics and Plant Breeding, volume for 1941, 325
Indian Plants, New Descriptions of some (Bor, Dr. N. L.), 417
Indian Science Congress, presidents of the sections of the 1943 session, 607
Indian Timbers for Tool Helves and Handles (Limaya, V. D.), 279
Indicator Organism for Activated Sludge, Vorticella as an (Reynoldson, T. B.), 608
Individuality and Science (Blakeslee, Dr. A. F.), 288
Indo-Australian Archipelago, Biogeographic Division of the (Scrivenor, J. B.), 556
Industrial Laboratory, X-Ray Technique in the (Rooksby, H. P.), 597
Industrial Needs (Raw Materials and): Mineral Resources and Outlook (Division for the Social and International Relations of Science of the British Association Conference on), 576
Industrial Poisons, Hazards and Solvents, The Analytical Chemistry of (Jacobs, Dr. Morris B.), *review*, 179
Industrial Processes, Infra-Red Radiation and Equipment, their Application to (Maxted, R.), 192
Industry, The Direct-Current Amplifier in (Gall, D. C.), 436; Electronics in, 278; Infra-Red Radiation in, 192; Plastics in ("Plastes"), second edition, *review* by Dr. E. F. Armstrong, 682; X-Ray Analysis in (Institute of Physics Conference on), 166, 503; and its Hazards, *review*, 179; and Rural Life (Town and Country Planning Association Conference on), 354; in Scotland, 577; and Town Planning (Pumphrey, Roland), 588
Industry (Defence of), Design of Protective Structures and the (Baker, Prof. J. F.), 673
Industry (Engineering), Gas Contamination Problem in the, with special reference to Electrical Machinery (Martin, J. W.), 673
Influenza A Virus (Chambers, Leslie A., and Henle, Werner), 304
Information, Ministry of, Sir John Russell appointed adviser to the Soviet Relations Branch of the, 108
Infra-Red Radiation and Equipment, their Application to Industrial Processes (Maxted, R.), 192
Inheritance (Polygenic) and the Drosophila Culture (Gordon, Dr. C., and Sang, J. H.), 610
Inheritance in the Grasshopper (Creighton, M., and Robertson, W. R. B.), 222
Inheritance (Size) in Tomatoes (MacArthur, J. W.), 113
Inhibition of Growth by Chemical Compounds (Badger, G. M., *et al.*), 275
Injured Cells, Relation of Aeration to the Activity of Proliferation-Promoting Factors from (Loufbourow, Prof. John R., Webb, Dr. Alfred M., and Abramowitz, Rosaline K.), 272
Injury (Modification of) Produced by Röntgen Radiation (Evans, T. C.), 24
Inland Fisheries, Irish Sea and, report of the Minister for Agriculture (Eire) for 1940, 605
Innervation (Afferent) of Mammalian Abdominal Viscera (Burns, W.), 221
Innes (John) Horticultural Institution, report of the thirty-second year, 728
Insect Ecology, Properties of Cuticle and (Uvarov, Dr. B. P.) 109; (Kalmus, Dr. H.), 109
Insecticidal Sprays, Biological Assay of (Parkin, Dr. E. A.), 720
Insects, Biotin as a Possible Growth Factor for (Fraenkel, Dr. G., and Blewett, M.), 301; Memory in (Thorpe, W. H.), 113
Insemination (Artificial) of Cattle, 438
Instruments, Aircraft (Irvin, George Ellis), *review*, 593
Insulating Oil in relation to Circuit-Breaker Failures (Cooper, W. Fordham), 703
Insulating Oils, (Institution of Electrical Engineers discussion on), 703; for Cables (Beckinsale, S.), 703; Maintenance of, in the Field (Welch, L. H.), 703
Insulation, Field Measurements of (Burton, E. A., Forrest, J. S., and Warren, T. R.), 415
Insulation (Wire), Cellulose Acetate Yarn for (Brobst, D. R.), 437
Insulators, High-voltage Porcelain (Forrest, J. S.), 276
Inter-American Relations, 106
International Aspects of Reconstruction, 201
International Commission on Continental and Oceanic Structure to continue the Scoresbysund Seismological Station, 136
International Economic Equilibrium, 311
International Relations, Leadership in, 479
International Science, The Nazi Attack on (Needham, Dr. Joseph), 215
International Seismological Summary, July–September 1934 (Bellamy, Miss E. F.), 380
Interstellar Lines in the Laboratory (Douglas, A. E., and Herzberg, G.), 142
Intertidal Sand of Kames Bay, Millport, Buteshire, The Macrofauna of the (Watkin, E. Emrys), 670
Intestine, Emulsification and Absorption of Fats and Paraffins in the (Frazer, A. C., Stewart, H. C., and Schulman, Dr. J. H.), 167
Intuition and Higher Space (Randall, M., and Longtin, B.), 114
Invention (Advance in), its Relation to World Peace (Jones, D. Caradog), 542
Invention (Scientific) at the Service of the Community (Langdon-Davies, Capt. John), 298
Inventions (Impact of) on People, *review* by D. Caradog Jones, 63
Ionosphere, The Sun and the (Chapman, Prof. Sydney), 277, *erratum*, 354
Ionospheric Measurements during Total Solar Eclipse (Higgs, A. J.), 701
Ipswich Man, presented to the Ipswich Museum, 578

Iraq, Meteorology in, fifth annual report of the Director of the Meteorological Service for the year ending March 31, 1941, 606
Ireland, Microlepidoptera of (Beirne, B. P.), 52
Irish Fisheries, 30
Irish Sea and Inland Fisheries, report of the Minister of Agriculture (Eire) for 1940, 605
Iron Group in Analysis, Adsorption of Metals in the (Austin, G. J.), 276
Iron Ore, Wealden, 134
Iron (Preservation of) by Paint, Laboratory Test for (Gibney, R. B.), 250
Iron and Steel Institute, Bessemer Gold Medal for 1942 awarded to Eugene G. Grace, 75
"Isms", Beyond the (Stapledon, Olaf), *review* by F. S. Marvin, 593
Isobutene (Catalytic Dimerization of) by Activated Copper Sulphide (Wassermann, Dr. A., and Weller, W. T.), 669
Isotopes, Mass Spectra and (Aston, Dr. F. W.), second edition, *review* by Prof. James Kendall, 680; Separation of (Thode, H. G., and Walkling, F. O.), 700
Isotopic Shift of Potassium in Human Bone-marrow and Cancer (Lasnitzki, Dr. A., and Brewer, Dr. A. K.), 357
Italy, Earthquakes on November 10, 1941, and on January 2, 1942, 636
Ives (Frederick) Medal of the Optical Society of America, awarded to Dr. Selig Hecht, 136

JACKSON (Herbert) Prize for 1941, awarded to S. Bairstow, 299
Jackson-Gwilt Medal and Gift of the Royal Astronomical Society, awarded to Dr. R. L. Waterfield, 217
Jamaica, Principal Timbers of (Swabey, C.), 379
Japan and the Modern World (Pratt, Sir John), 606
Jeffries (John) award of the American Institute of the Aeronautical Sciences, given to Major Harry G. Armstrong, 469
Jerusalem, Hebrew University, 354
Jig Borer Microscope ("Watts"), 497
Journey, A Sentimental, *review* by Prof. J. L. Myres, 449
Judd (Kathleen Berkan) 1,000 dollar prize awarded to Prof. Louis Fieser, 47
Jung (C. G.), The Psychology of (Jacobi, Dr. Jolan), *review* by Dr. Clifford Allen, 622

KALSILITE-BEARING Volcanic Rocks in Uganda (Holmes, Prof. A.), 223
Kamala the Wolf Girl, The Life History of (Gesell, Dr. Arnold), *review*, 181
Keith Prize of the Royal Society of Edinburgh, awarded to Prof. E. T. Copson and Prof. W. H. McCrea for 1939–41, 268
Kelvin Lecture of the Institution of Electrical Engineers (Chapman, Prof. Sydney), 277, *erratum*, 354
Kenya and Abyssinia, Pleistocene Climates in (Kent, P. E.), 736
Ketones (Unsaturated), Absorption Spectra of (Evans, L. K., and Gillam, A. E.), 333
Ketosteroids (Excretion of) in Human Pregnancy Urine in Relation to the Sex of the Fœtus (Burrows, Dr. Harold, MacLeod, Douglas H., and Warren, F. Ll.), 300
Kew, Earthquakes registered during February 2–March 5, 1942, 409; Earthquakes registered during March 8–April 7, 1942, 469; Earthquakes registered on April 8, on April 13, and between April 15–May 5, 1942, 578; Earthquakes registered on May 14, 1942, 694
Kinetic Friction, Mechanism of (Bristow, J. R.), 169
Kinetics (Chemical) of Organic Reactions in Liquid Systems, Mechanism and (Hughes, Dr. E. D.), 126
Kiss, The Origin of the, and other Scientific Diversions (Beadnell, Surgeon Rear-Admiral C. M.), *review* by T. Raymont, 713
Klino-kinesis in Paramecium (Gunn, Dr. D. L.), 78
Knotted String, Autobiography of a Steel-maker (Brearley, Harry), *review* by Dr. C. H. Desch, 397
Knowledge (Scientific) among British Farmers, The Better Dissemination of (Parliamentary and Scientific Committee discussion on), 722
Knowledge and Action, 647

LABORATORY (Industrial), X-Ray Technique in the (Rooksby, H. P.), 597
Labour, Life and, *review* by Sir Richard Gregory, 678
Labour Wastage, Hours of Work, Lost Time and (Medical Research Council, Industrial Health Research Board, Emergency Report No. 2), 281
Labour and Management in Reconstruction, 559
Labour and National Service, Ministry of, Appointments Department of the, 496
Lactic Dehydrogenase of Yeast (Bach, S. J., Dixon, Dr. Malcolm, and Zerfas, Dr. L. G.), 48
Lactose and Maltose (Detection of) by means of Methylamine (Fearon, W. R.), 305
Lakes, Biological Productivity of (Juday, C.), 24
Land, Reconstruction and the, an Approach to Farming in the National Interest (Hall, Sir A. Daniel), 13
Landscape as Developed by the Processes of Normal Erosion (Cotton, C. A.), *review* by Prof. A. E. Trueman, 60
Landscape Features, Origin of, *review* by Prof. A. E. Trueman, 60
Lantern Slides, Diagrams and Formulæ for (Chibnall, Prof. A. C.), 327; (Minnis, J. W.), 327
Lathridiidæ, Beetles of the Family (Hinton, Dr. H. E.), 141
Layman, Scientific Aids for the, *review* by T. Raymont, 713
Leadership in International Relations, 479; for the New Order, 619; in World Reconstruction, 337
Leaf (Silver) Disease (Ministry of Agriculture Advisory Leaflet No. 246), 635
Leaf-beetles Collected by Charles Darwin (Bryant, G. E.), 379
Leaf-Curl Virus Diseases (McClean, A. P. D.), 304
Leaves (Green) as a Source of Proteins and other Nutrients (Pirie, N. W.), 251
Lecithinase Activity of *Cl. welchii* Toxins (Macfarlane, M. G., and Knight, B. C. J. G.), 222
Leeches, 437
Leeds General Infirmary, new teaching departments at, 108
Leicester Literary and Philosophical Society (Ornithological Section), report and status of birds for 1941, 378
Leicestershire, Birds of, 74
Lens Systems, Thermal Effects on the Performance of (Perry, J.), 324
Leprosy in Brazil, 636
Lettuce, Value of Molybdenum for (Brenchley, Dr. W. E., and Warington, Dr. K.), 196
Levan, Enzymatic Synthesis of (Aschner, M., Avineri-Shapiro, S., and Hestrin, Dr. S.), 527
Libraries (University), Books for Damaged, 434
Libya, Geology of (Sandford, K. S.), 389
Lice (Smart, Dr. John), 354
Liebefeld Research Institute, Advances in the Knowledge of Bee Diseases, 222
Liesegang Phenomenon, Silica and the (Copisarow, Alcon C., and Copisarow, Dr. Maurice), 413
Life, The Problem of the Autonomy of, *review* by Prof. F. G. Donnan, 394, 551; (Kapp, Prof. Reginald O.), 551; (Beadnell, Surgeon Rear-Admiral Charles M.), 551
Life and Labour, *review* by Sir Richard Gregory, 678
Light, The Chemical Aspects of (Bowen, E. J.), *review* by Dr. C. H. Bamford, 714; Living (Harvey, E. Newton), *review* by Sir D'Arcy W. Thompson, 258
Light (The Efficient Production of) by the Electric Discharge (Francis, V. J.), 278
Light (Fluorescent) Sources (Aldington, J. N.), 466
Light Penetration, Water Transparency and (Clarke, G. L.), 476
Lighting, B.A.B. Fluorescent System of (Colloidal Research Laboratories, Ltd.), 106; Fluorescent (Davies, L. J., Ruff, H. R., and Scott, W. J.), 577
Lighting (Street), Past, Present and Future (Wilson, G. H.), 576
Lightning in Nigeria, Investigations on, 198

Lightning Discharge, The (Bruce, C. E. R., and Golde, R. H.), 224
Lightning Voltages and Currents in Nigeria, The Measurement of, Part 2, 1938–1939 (Ferry, F. R., Webster, G. H., and Baguley, P. W.), 198
Linde (Carl von), a Pioneer of 'Deep' Refrigeration (Awbery, J. H.), 630
Linkage of Physico-Chemical Processes in Biological Systems (Conway, Prof. Edward J.), 383, *erratum*, 438; (Donnan, Prof. F. G.), 383
Linkage Studies, in the Fowl (Hutt, F. B.), 276; in the Rabbit (Castle, W. E., and Sawin, P. B.), 276
Linnean Society of London, meetings of the, 108; discussion on the Biogeographic Division of the Indo-Australian Archipelago, 556; election of officers for the year 1942–43, 636; discussion on Seed Germination, 658
Lipoidal Spectra (Fluorescent) of Human Tissue (Penn, Dr. H. S.), 193
Lipoids (Behaviour of) in Human Serum (McFarlane, Dr. Arthur S.), 439
Liquefaction Plant for Natural Gas, 635
Liquid Systems, Mechanism and Chemical Kinetics of Organic Reactions in (Hughes, Dr. E. D.), 126
Liquids (Flow of) in the Critical Region (Nissan, Dr. Alfred H.), 501
Liquids and Gases, Measurement of the Flow of (Ower, E.), 333
Lithium Alum (Horan, H. A., and Duane, J. J.), 250
Liverpool Area, The Birds of the (Hardy, Eric), *review* by R. K. Perry, 287
Livestock, Seaweed as a Food for (Beharrell, J.), 306
Living, Plan for, the Architect's Part (Williams-Ellis, Clough), 589
Living Light (Harvey, E. Newton), *review* by Sir D'Arcy W. Thompson, 258
Lodgewood Telegraph Poles (Amadon, C. H.), 467
Logan, Utah, The Oldham Seismograph Station at Utah State Agricultural College (Williams, J. Stewart), 585
London Scientific Film Society, 617
London, University of, conferment of degrees of D.Sc., 270; William Julius Mickle Fellowship awarded to Prof. Alexander Fleming, 270; Certificate in Natural History, 327
London (Washington and), Agricultural Advisers in, 549
Low-Temperature Research and Development in the Soviet Union (Ruhemann, Dr. M.), 546
Lowland Tropical Podsols in Uganda (Thomas, A. S.), 195
Luminous Paint, 106
Luminous Phenomenon accompanying the Cyprus Earthquake, January 20, 1941 (Aziz, Abdulazim), 640
Luminous Strontium Sulphide (Rothschild, Dr. S.), 106
Lupane Derivatives, Surface Films of (Bilham, P., Jones, E. R. H., and Meakins, R. J.), 415
Lyell Fund of the Geological Society of London, a moiety awarded to Dr. S. R. Nockolds, 135; a moiety awarded to Dr. J. Shirley, 135
Lyell Medal of the Geological Society of London awarded to W. S. Bisat, 135
Lymph, The Study of, *review* by J. C. Mottram, 65
Lymphatics; Lymph and Lymphoid Tissue (Drinker, Prof. Cecil Kent, and Yoffey, Dr. Joseph Mendel), *review* by J. C. Mottram, 65

McCORMICK (Leander) Proper Motions (Ali, A.), 142
Machine Design Drawing Room Problems (Albert, Prof. C. D.), third edition, *review*, 205
Machinery (Electrical), Gas Contamination Problem in the Engineering Industry, with special reference to (Martin, J. W.), 673
Machines, Mathematical (Lilley, Dr. S.), 462
Macnab (William) Medal of the Institution of Chemical Engineers, awarded to E. W. Pates, 409
Macrofauna of the Intertidal Sand of Kames Bay, Millport, Buteshire (Watkin, E. Emrys), 670
Macropinna microstoma (Bathypelagic Fish), The Osteology and Relationships of the (Chapman, Wilbert McLeod), 700
Madras (the South of), North-east Monsoon Rainfall of (Iyer, V. Doraiswamy), 670
Magnesium, Gravimetric Micro-determination of (Holt, P. F.), 642
Magnetic Field, Torque on a Silicon Iron Crystal in a (Bozorth, R. M., and Williams, H. J.), 359
Magnetic Storms, Cosmic Rays and (Duperier, Dr. A.), 579
Magnetism in Relation to Chemical Problems (Mathur, Dr. K. N., *review* by Dr. W. Rogie Angus, 396
Magnetism (Electricity and), A Laboratory Manual of (Loeb, Leonard B.), revised edition, *review*, 181
Magnetochemistry, *review* by Dr. W. Rogie Angus, 396
Magnetostriction (Brailsford, F., and Martindale, R. G.), 701; in Permalloy (Williams, H. J., Bozorth, R. M., and Christensen, —.), 359
Magnitudes and Colours of Northern Stars, 53
Maintenance of Insulating Oils in the Field (Welch, L. H.), 703
Maintenance of Shade and Ornamental Trees (Pirone, Prof. P. P.), *review* by Fraser Story, 314
Malaya, Forestry in, 307
Malaya including Brunei, Annual Report on Forest Administration in, for the year 1940 (Watson, J. G.), 307
Malayan Wild-Life, 17, 75
Malnutrition, The Extent, Causes and Cure of (Sinclair, Dr. H. M.), 208
Malnutrition (Poverty and) in South Africa, Remedies for (Osborn, Dr. T. W. G.), 18
Maltose and Lactose (Detection of) by means of Methylamine (Fearon, W. R.), 305
Mammalian Abdominal Viscera, Afferent Innervation of (Burns, W.), 221
Mammalian Arm Arteries, 414
Mammals of India, *review* by D. Seth-Smith, 122
Man, Science and (Newsholme, Dr. H. P.), 516
Man Who Lived for To-morrow, a Biography of William Hallock Park, M.D. (Oliver, Wade W.), *review*, 230
Man (Early) in New Mexico (Hibben, F. C.), 222
Man (Modern Stone-Age) in South Australia, 641
Man and Animals (Rival Claims of) for Food (Wright, Dr. N. C.), 318
Management (Labour and) in Reconstruction, 559
Mankind, Medicine and (Sorsby, Arnold), *review* by Dr. Joseph Geoghegan, 233
Man-Power, Scientific Utilization of, 531
Man-Power (Skilled) in the Services, 255
Man's Achievement of Flight, *review* by Capt. J. L. Pritchard, 231
Man's Present and Future, *review* by Rev. J. C. Hardwick, 316
Manufacture, Quality Control in (Rissik, H.), 408; (Dudding, Bernard P.), 555
Marburg, University of, foundation of an Emil von Behring prize, 665
Marchant Calculating Machine (The Twin) and its Application to Survey Problems (Comrie, Dr. L. J.), *review*, 425
Marine Research in the United States (Deacon, G. E. R.), 363
Marsupial Heart, Age Changes in Size of Muscle Fibres of the (Davies, Prof. Francis, and Francis, Dr. Eric T. B.), 410
Marsupial *Trichosurus vulpecula*, Effect of Chorionic Gonadotropin on the Pouch of the (Bollinger, Dr. A.), 440
Marx Memorial Library and Workers' School, Symposia at the London School of Hygiene and Tropical Medicine, 327; Symposium on The Scientific Attitude to Fascism with particular Reference to Racial Theories, 327, 426; Symposium on Science and Technology in the Soviet Union, 327, 545
Mass of the Mesotron, A Photographic Method of Estimating the (Bose, Dr. D. M., and Choudhuri, Miss Bibha), 302
Mass Spectra and Isotopes (Aston, Dr. F. W.), second edition, *review* by Prof. James Kendall, 680
Massachusetts Institute of Technology and the Optical Society of America, Conference on Spectroscopy and its Applications, 665
Materialism, Science versus (Kapp, Prof. Reginald O.), *review* by Prof. F. G. Donnan, 394, 551
Materials, Those Raw (Ward, C. A.), *review* by Dr. E. H. Tripp, 178

Materials (Raw) and Industrial Needs: Mineral Resources and Outlook (Division for the Social and International Relations of Science of the British Association Conference on), 576
Materials and Structures (Clark, D. A. R.), *review*, 563
Mathematical Bases, Statistical Procedures and their (Peters, Dr. Charles C., and van Voorhis, Prof. Walter R.), *review*, 151
Mathematical Machines (Lilley, Dr. S.), 462
Mathematical Requirements for Statistics, *review*, 151
Mathematical Statistics, Committee Decisions and (Nicol, Dr. Hugh), 473
Mathematics, Practical (Durell, Clement V.), *review*, 486
Mathematics for Engineers (Dull, Raymond W.), second edition, *review*, 125
Mathematics for Technical Students (Geary, A., Lowry, H. V., and Hayden, Dr. H. A.), Part 3, *review*, 453
Measurement, Colour (Smith, T., Guild, Dr. J., and Donaldson, R.), 76; (Harrison, Dr. V. G. W.), 76; (Perry, J. W.), 247, 553; (Guild, J.), 442; Purity and Fine, *review* by Prof. A. C. Egerton, 229; of Radiation for Medical Purposes (Mayneord, Prof. W. V.), 600
Measurements (Field) of Insulation (Burton, E. A., Forrest, J. S., and Warren, T. R.), 415
Measurements (Precision), An Improved Capacitance Bridge for (Voelker, W. D.), 468
Measures, Octonarian Weights and, 106
Mechanism and Chemical Kinetics of Organic Reactions in Liquid Systems (Hughes, Dr. E. D.), 126
Mechanism of Kinetic Friction (Bristow, J. R.), 169
Mechanism of the Sun (Sellers, F. J.), 136
Mechanisms of Vision (Hecht, Prof. Selig), 40
Medical Advances in the Argentine (Houssay, Dr. B. A.), 437
Medical History of the War, 47
Medical Progress in China (Woo, Dr. W. H.), 522
Medical Purposes, Measurement of Radiation for (Mayneord, Prof. W. V.), 600
Medical Research, National Institute of, Sir Henry Dale to retire from the post of director, 633; Prof. C. R. Harington to succeed Sir Henry Dale as director, 633
Medical Research Council, Prof. A. W. M. Ellis appointed director of research in industrial medicine, 270; Radiotherapeutic Research Unit, 216; Studentship for Training in Methods of Experimental Psychology, 75
Medical Schools, Committee on, 382
Medical Service (School) in War-time (Glover, Dr. J. Alison), 550
Medical Services in Sweden (Trietz, Torsten), 468
Medical Theory and Practice, *review*, 285
Medicine, The Advancing Front of (Gray, George W.), 285; Influence of Snobbery on the Practice of (Jones, Dr. W. H. S.), 529; The Sociology of, *review* by Dr. Joseph Geoghegan, 233
Medicine (Clinical) Chemistry in, *review* by Dr. Joseph Geoghegan, 485
Medicine (Hippocratic), its Spirit and Method (Heidel, William Arthur), *review* by Dr. W. H. S. Jones, 422
Medicine (Historical) and Science, Schuman's catalogue of books on, 498
Medicine and Mankind (Sorsby, Arnold), *review* by Dr. Joseph Geoghegan, 233
Meiosis in Drosophila (Philip, Ursula), 527
Meiosis (Mitotic Divisions following) in *Pediculus corporis* Males (Hindle, Prof. E., and Pontecorvo, G.), 668
Melchett Medal of the Institute of Fuel awarded to Dr. Arno Carl Fieldner, 523
Memory in Insects (Thorpe, W. H.), 113
Men (Why) Behave Like Apes and Vice Versa (Hooton, Earnest Albert), *review* by Dr. S. Zuckerman, 340
Men (Skilled) in the Services, Second Report of War Office Committee, 255
Mercerizing (Marsh, J. T.), *review* by Prof. J. B. Speakman, 3
Merseyside Naturalists' Association, annual meeting, 382
Mesotron (Mass of the), A Photographic Method of Estimating the (Bose, Dr. D. M., and Choudhuri, Miss Bibha), 302
Metabolic Products of 3 : 4-Benzpyrene (Berenblum, Dr. I., and Schoental, R.), 439
Metabolic Products (Certain Bacterial) on Soil Protozoa, Toxic Effects of (Singh, Dr. B. N.), 168
Metallurgy (Soviet), Faculty of Science, Marx House Discussion on, 578
Metals, A Type of Plastic Deformation New in (Orowan, Dr. E.), 643; A Theory of the Strength of (Bragg, Sir Lawrence), 511; X-Ray Study of the Elastic Constants of (Lonsdale, Dr. K., and Smith, H.), 21
Metals (Adsorption of) of the Iron Group in Analysis (Austin, G. J.), 276
Metals, Institute of, Platinum Medal awarded to W. Murray Morrison, 135; W. T. Halcrow to deliver the thirty-second May Lecture, 299, *erratum*, 327; Sir John Greenly elected president for 1942–43, 327
Metasomatic Origin of Granophyre, 414
Metchnikoff (Elie), The Scientific Work of (Petrie, Dr. G. F.), 547
Meteorites and the Age of the Solar System (Arrol, W. J., Jacobi, R. B., and Paneth, Prof. F. A.), 235
Meteorologcial Research in Great Britain, 544
Meteorological Society, Royal, election of Prof. D. Brunt as president of the, 189; Symons Memorial Lecture to be delivered by Dr. H. Spencer Jones, 217; Annual Phenological Report for the year 1941, 497; presidential address on Electricity and Rain (Simpson, Sir George), 659
Meteorological Time Series, The Problem of Auto-correlation of (Schumann, T. E. W., and Hofmeyer, W. L.), 414
Meteorology, An Introduction to (Petterssen, Prof. Sverre), *review* by Prof. D. Brunt, 423; in Art, 326; in Burma, 379; in Iraq (Fifth annual report of the Director of the Meteorological Service for the year ending March 31, 1941), 606; of Rhodesia, 269; Scenic Approach to (Bonacina, L. C. W.), 326; Visibility in (Middleton, W. E. Knowles), second edition, *review* by E. V. Newnham, 155
Meteorology (Agricultural) in India, 216
Meteors, Whistling (Venkataraman, Chamanlal and K.), 416
Methodology of Pierre Duhem (Lowinger, Armand), *review* by Dr. H. Jeffreys, 564
Methodology (Statistical), The Second Yearbook of Research and (edited by Buros, Oscar Krisen), *review*, 9
Methylamine, Detection of Lactose and Maltose by means of (Fearon, W. R.), 305
Methylcholanthrene, Fluorescence of (Hieger, Dr. I.), 300
Mexico, National Astrophysical Observatory of, 73, 353
Mickle (William Julius) Fellowship of the University of London, awarded to Prof. Alexander Fleming, 270
Microbial Synthesis and Autolysis in the Digestive Tract of Herbivora (Baker, Frank), 582
Microbiological Assay of Riboflavin in Cereals (Barton-Wright, Dr. E.), 696
Microbiology of the Atmosphere, 387
Micrcoulomb Experiment, The (Ehrenhaft, Prof. F.), 25
Micro-determination (Gravimetric) of Magnesium (Holt, P. F.), 642
Microfauna of Cattle, Normal Rumen Microflora and (Baker, Frank), 220
Microlepidoptera of Ireland (Beirne, B. P.), 52
Microphotometer, A New Type of (Fürth, Dr. R.), 730
Microscope, The X-Ray (Bragg, Sir Lawrence), 470; "Watts" Jig Borer, 497
Microscopical Society, Royal (1839–1939), 324
Microscopy (Chemical), Handbook of (Chamot, Prof. Émile Monnin, and Mason, Prof. Clyde Walter), Vol. 2: Chemical Methods and Inorganic Qualitative Analysis, second edition, *review*, 593
Middlesex (The Place-Names of), apart from the City of London (Gover, J. E. B., Mawer, Allen, Stenton, F. M., and Madge, S. J.), *review* by Sir Charles Peers, 370
Midlands, Birds of the, 378
Military Service (Fitness for) in the United States, 388
Milk Production and Utilization, The Application of Science to the War Effort in (Kay, Prof. H. D.), 208
Milky Way, Rotation of the, 74
Mind (Class) and Group Mind (Flugel, Prof. J. C.), 488
Mineral Oil for Transformers and Switchgear (Pollitt, A. A.), 703
Mineral Resources and the Atlantic Charter (Division for the Social and International Relations of Science of the British Association Conference on), 728

Mineral (World) Resources and Post-War Needs, 576
Mining and Metallurgy, Institution of, J. Allen Howe elected president for 1942–43, 135
Mitochondria, Chemical Composition of (Baker, Dr. John R.), 611
Mitosis, in Amœbæ (Taylor, Dr. Monica, and Hayes, Carmela), 501; in Tumours, A New Technique for (Koller, Dr. P. C.), 193
Mitotic Divisions following Meiosis in *Pediculus corporis* Males (Hindle, Prof. E., and Pontecorvo, G.), 668
Mock Sun at Hitchin (Cave, L. C. H.), 46
Modern Science and Musical Theory (Lloyd, Ll. S.), 389
Modern Science and Thomas Hobbes (Bell, A. E.), 688
Moisture, Determination of (Vincent, R. S., and Simons, A.), 170
Molybdenum for Lettuce, Value of (Brenchley, Dr. W. E., and Warington, Dr. K.), 196
Monaghan (Co.), Ireland, A Late-Glacial Flora in (Mitchell, G. F.), 502
Monetary System, A Proposed Reformed (Cole, G. D. H.), 173
Monkey (Rhesus) (*Macaca mulatta*), Embryology of the, *review* by Dr. S. Zuckerman, 592
Monosomics, Transmission of (Greenleaf, W. H.), 52
Monsoon Rainfall, Forecasting (Iyer, V. Doraiswamy, and Seshachar, C.), 280
Moon (the Mass of the), The Solar Parallax and (Jones, Dr. H. Spencer), 333
Morocco, Pleistocene Raised Beaches on the West Coast of (Breuil, Abbé H.), 77
Morphology of a Cicada (Evans, J. W.), 249
Mortimer Museum, Hull, Bronze Age Implements in the (Sheppard, T.), 694
Mosquito-Breeding in Static Water Supplies (Marshall, J. F.), 568; (Marshall, J. F., and Attwooll, K. W.), 352
Mosquito Control, Indian Fishes and, 644
Mould (Vegetable) through the Action of Worms", A Postscript to Darwin's "Formation of (Keith, Sir Arthur), 716
Moulton Medal of the Institution of Chemical Engineers, awarded to P. Parrish, 409; Junior Moulton Medal for 1941 not awarded, 409
Mount Palomar Observatory, closing of, 47
Mounting Medium, A Substitute for Glycerine as a (Harris, Prof. T. M.), 554
Mouse Ovary, Effect of Œstrin Injections on the (Bullough, Dr. W. S.), 271
Mucorales, Spore Dispersal in the (Dobbs, Dr. C. G.), 583
Mucus, Elasticity of Bovine Cervical (Blair, Dr. G. W. Scott, and others), 222
Müller (Hugo) Lecture on Some Aspects of Algal Chemistry (Heilbron, Prof. I. M.), 398
Murchison Fund of the Geological Society of London, awarded to Dr. K. C. Dunham, 135
Murchison Medal of the Geological Society of London, awarded to Prof. H. H. Swinnerton, 135
Muscle Fibres of the Marsupial Heart, Age Changes in Size of (Davies, Prof. Francis, and Francis, Dr. Eric T. B.), 410
Muscles *in vitro* (Decrease in Glycogen Phosphorylation in) after Adrenalectomy and Restoration with Desoxycorticosterone (Verzár, Prof. F., and Montigel, C.), 49
Music, The Anthropological Approach to the Study of (Angold, F. H.), 186
Musical Notation, Simplification of (Brabazon of Tara, Lord), 554; (Lloyd, Ll. S.), 640; (Wood, Kenneth B.), 640; (Harrison, Dr. V. G. W.), 733
Musical Theory, Modern Science and (Lloyd, Ll. S.), 389
Mustard, Vernalization of (Sen, Dr. B., and Chakravarti, S. C.), 139

NANYIKALAND, Pottery-making in (Martin, C.), 225
α-Naphthalene Acetamide, Breakdown of Self-Incompatibility by (Lewis, D.), 610
National Astrophysical Observatory of Mexico, 73, 353
National Bread (Staff of the Research Association of British Flour-Millers), 460
National Central Library, Twenty-fifth annual report of, 107
National Institute of Agricultural Botany, Special Seed Production Committee, 299
National Institute of Economic and Social Research, 416
National Institute of Hygiene, founded in Paris, 636
National Life, Nature Preservation and, 1, 75
National Wheatmeal (Storage of), Report by the Research Association of British Flour-Millers, 635
Nationality (Race,) and Class (Torr, Miss Dona), 427
Native Subsistence Economics (Environment and) in the Central Great Plains (Wedel, W. R.), 145
Natural History, Canadian, *review* by Dr. A. E. Cameron, 154; University of London Certificate in, 327
Natural Science in German Romanticism (Aesch, Alexander Gode-von), *review* by Prof. A. Wolf, 104
Naturalist in Canada, A (McCowan, Dan), *review* by Dr. A. E. Cameron, 154
Nature Abounding (edited by Watson, E. L. Grant), *review*, 287
Nature Preservation, and National Life, 1, 75; in Post-War Reconstruction, 2
Nature, Education and, *review* by T. Raymont, 651
Navigation (Air) Stars, The Observer's Planisphere of (Chichester, Ft.-Lieut. Francis), *review* by Dr. H. Spencer Jones, 450
Navigation by the Stars (Astrographics, or First Steps in) (Debenham, Prof. Frank), *review* by Dr. H. Spencer Jones, 450
Nazi Attack on International Science (Needham, Dr. Joseph), 215
Nazism and Science, 215
Neill Prize of the Royal Society of Edinburgh, awarded to Dr. P. C. Koller and Dr. W. J. McCallien for 1939–41, 268
Nematocysts, Excitation of (Pantin, Dr. C. F. A.), 109
Nematode (Resistance of a Soil) to Changes in Osmotic Pressure (Stephenson, Dr. William), 500
Nervous Shock in Peace and War (Brend, Dr. William A.), 324
Nervous System, Diseases of the (Walshe, Dr. F. M. R.), second edition, *review* by Dr. C. M. Hinds Howell, 64
Neurology for Students and Practitioners, *review* by Dr. C. M. Hinds Howell, 64
Neurospora, Physiological Genetics of (Beadle, G. W., and Tatum, E. L.), 249
Neutrons in Deuterium, Scattering of (Sundarachar, Prof. C. K., and Streib, Dr. J. F.), 51
New England, Hurricane Floods of September 1938 in (Brooks, Dr. C. E. P.), 556; Seismic Surveying in, 380
New Guinea, Earthquake on January 27, 1942, 434
New Mexico, Early Man in (Hibben, F. C.), 222
New Order, Leadership for the, 619
New South Wales, Earthquakes registered in, during July–September 1941, 380
New York City Memorial Hospital for the Treatment of Cancer and Allied Diseases, Kathleen Berkan Judd 1,000 dollar prize awarded to Prof. Louis F. Fieser, 47
New Zealand, Earthquakes during 1940, 443; registered during February 1942, 636; Earthquake Origins in (Hayes, R. C.), 146; Forests of, 672; Annual Report of the State Forest Service for the Year ending March 31, 1941 (Entrican, Alex. R.), 672
Newton Tercentenary, Physical Society celebration of, 192
Newtonian Attraction, An Introduction to the Theory of (Ramsey, A. S.), *review* by Prof. L. M. Milne-Thomson, 180
Niagara Falls, Rainbow Bridge over the, 326
Nigeria, Investigations on Lightning in, 198
Nitrogen (Activation of) in the Silent Electric Discharge (Joshi, S. S., and Purushotham, A.), 250
Nitrogenous Character of Penicillin (Abraham, Dr. E. P., Baker, W., Chain, Dr. E., Florey, Prof. H. W., Holiday, E. R., and Robinson, Sir Robert), 356
Nitzschia Cultures at Hull and at Plymouth (Wilson, D. P., and Lucas, C. E.), 331
Nobel Laureates in the United States, 216
Nobel (Alfred) Prize of the American Institute of Electrical Engineers, awarded to Robert F. Hays, jun., 438
Noise, Transformer (Swaffield, J.), 738
North East Land, The Latest Map of (Glen, A. R.), 107
Norway, Suppression of Culture in, 407

Notation (Musical), Simplification of (Brabazon of Tara, Lord), 554; (Lloyd, Ll. S.), 640; (Wood, Kenneth B.), 640; (Harrison, Dr. V. G. W.), 733
Nucleic Acid from Irradiated Yeast, Further Observations on the Increased Yield of (Loofbourow, Prof. John R., Webb, Alfred M., Loofbourow, Dorothea G., and Lisco, Hermann), 328
Nutrients, Green Leaves as a Source of Proteins and Other (Pirie, N. W.), 251
Nutrition, Food Production and (Pirie, N. W.), 318
Nutrition (Calcium) of the Fœtus (Duckworth, Dr. John), 731
Nutrition and the War (Bourne, Dr. Geoffrey), second edition, *review* by Dr. S. K. Kon, 453, 666
Nutrition Society, Conference on Food Production and Distribution in relation to Nutritional Needs, 192, 318; Conference on Problems of Collective Feeding in War-time, 469, 685
Nutritional Needs, The Agricultural Implications of a Food Policy based on (Orr, Sir John), 318; Food and, 192

OBSERVATORY (National Astrophysical) of Mexico, 73, 353
Oceanographic Observations across the Straits of Florida (Montgomery, R. B.), 476
Oceanography, Recent Research in (Deacon, Dr. G. E. R.), 476
Octonarian Weights and Measures, 106
Œstrin Injections (Effect of) on the Mouse Ovary (Bullough, Dr. W. S.), 271
Oil (Insulating) in relation to Circuit-Breaker Failures (Cooper, W. Fordham), 703
Oil (Lubricating) at High Velocity Gradients, Anomalous Viscosity of (Neale, Dr. S. M.), 51
Oil (Mineral) for Transformers and Switchgear (Pollitt, A. A.), 703
Oil Provinces (Possible Future) of the United States and Canada (Symposium conducted by the American Association of Petroleum Geologists), *review*, 4
Oils (Insulating), Institution of Electrical Engineers discussion on, 703; for Cables (Beckinsale, S.), 703; Maintenance of, in the Field (Welch, L. H.), 703
Oils and Oil-Rosin Saturants for use in Electrical Equipment, Manufacture and Testing of (Thompson, A. W., and Wood-Mallock, J. C.), 703
Oldham Seismograph Station at Utah State Agricultural College, Logan, Utah (Williams, J. Stewart), 585
Ontogeny (Plant), A Study in (Burkill, I. H.), 387
Optical Glass, Some Problems relating to (Hampton, Dr. W. M.), 324; Production of, in Australia (Hartung, Prof. E. J.), 518; Manufacture of, in Canada, 735
Optical Images formed by Conical Refraction (Raman, Sir C. V., and Nedungadi, T. M. K.), 552
Optical Society of America, Frederick Ives Medal awarded to Dr. Selig Hecht, 136; Joint Conference with the Massachusetts Institute of Technology on Spectroscopy and its Applications, 665
Oranges, Ascorbic Acid in (Lampitt, Dr. L. H., and Baker, L. C.), 271
Order (New), Leadership for the, 619
Organization of Production, 507
Organization (Scientific) of Social Activities, 119
Orientation, Valency and (Copley, George Novello), 730
Origin of the Kiss, and other Scientific Diversions (Beadnell, Surgeon Rear-Admiral C. M.), *review* by T. Raymont), 713
Origin of Landscape Features, *review* by Prof. A. E. Trueman, 60
Origins of Human Graphic Art (Huxley, Prof. Julian S.), 637, 733; (Bowen, J. Leonard), 733
Oriri (Stopes, Marie C.), *review*, 287
Orissa, The University of, 59
Ornithology, British Trust for, Wood Pigeon Investigation, 191
Osmotic Pressure, Resistance of a Soil Nematode to Changes in (Stephenson, Dr. William), 500
Out-breeding Mechanism in Fungi, Heterothally as an (Mather, Dr. K.), 54
Ovary (Mouse), Effect of Œstrin Injections on the (Bullough, Dr. W. S.), 271
Overture to Planning (Osborn, F. J.), 31
Owenduff (Ballycroy) River, Salmon of the (Went, A. W. E. J.), 52
Oxford, University of, degree of Hon. D.Sc. conferred on the Rev. T. E. R. Phillips, 241
Oxford Vaporizer (Mendelssohn, Dr. K.), 132
Oxidation of Hydrocarbons at Low Temperatures (George, P., Rideal, Prof. E. K., and Robertson, A.), 601
Oxidation-Reduction Balance, The Colorimetric Determination of (British Drug Houses, Ltd.), third edition, 299
Oxides (Lower) of Boron (Ray, R. C., and Sinha, P. C.), 305
'Oxygen Trough' of Expiration (Mackay, Dr. Ian F. S.), 698

PACIFIC, Occurrence of Ctenodrilus in the (Berkeley, C.), 248
Pacific (Eastern), Rays and their Allies from the (Beebe, William, and Tee Van, John), 113
Pacific (North), Submarine Contours of the (Betz, F., and Hess, H.), 359
Pacific (South-western), Seismology in the, 243
Pacific Ocean, Earthquake south of Alaska on September 24, 1941, 165; Earthquake north of Hawaii on September 25, 1941, 165; Earthquake south of San José on March 1, 1942, 523; Earthquake to the west of Southern Chile on March 5, 1942, 523
Packing (Open) of Spheres (Melmore, Sidney), 412, 669
Packing Cases for Army Boots and Suggested Improvements (Limaya, V. D.), 279
Pact, Washington International, 45
Paint, Laboratory Test for Preservation of Iron by (Gibney, R. B.), 250; Luminous, 106
Palæolithic in England, Northern Fringe of the (Gibson, Dr. H. N.), 111
Palæoliths from the Worthing Archæological Area (Migeod, F. W. H.), 444
Palæozoic Faunas (Upper) of North Sikkim (Muir-Wood, Helen M., and Oakley, Kenneth P.), 172
Palestine, Health of, 19
Palestinian Coast, A Ctenophore from the (Haas, J.), 110
Pan-American League for the Control of Cancer, meeting at Buenos Aires, 136
Paper, Reflexion from (Burke, E.), 613; (Harrison, Dr. V. G. W.), 613; (Strachan, J.), 732; (Bowen, J. Leonard), 733; (King, Dr. J. Leycester), 733
Paracelsus as Physician, *review* by Dr. W. H. S. Jones, 510
Paraffins (Fats and) in the Intestine, Emulsification and Absorption of (Frazer, A. C., Stewart, H. C., and Schulman, Dr. J. H.), 167
Paramecium, Klino-Kinesis in (Gunn, Dr. D. L.), 78
Paranthropus robustus, The Hand of the Ape-Man (Broom, Dr. R.), 513
Paris Academy of Medicine, Committee to publish a list of drugs and chemical products becoming rare, 729
Park (William Hallock), The Life and Work of, *review*, 230
Parliamentary and Scientific Committee, First annual luncheon, 164; Discussion on the Better Dissemination of Scientific Knowledge among British Farmers, 722
Parthenogenetic Activation of Rabbit Eggs (Shapiro, Herbert), 304
Peace, Conditions of (Carr, Prof. Edward Hallett), 479; Reconstruction and ("Balbus"), 338
Peace (World), Advance in Invention, its Relation to (Jones, D. Caradog), 542
Peace Aims, Federal Union and, 434
Pear, A Useful Abnormality of the Pollen in a (Thomas, Dr. P. T.), 168
Pediculus corporis Males, Mitotic Divisions following Meiosis in (Hindle, Prof. E., and Pontecorvo, G.), 668
Pelage in the Stoat, *Mustela erminea* L., Change of (Rothschild, Hon. Miriam), 78
Penicillin, Nitrogenous Character of (Abraham, Dr. E. P., Baker, W., Chain, Dr. E., Florey, Prof. H. W., Holiday, E. R., and Robinson, Sir Robert), 356; Purification of (Abraham, Dr. E. P., and Chain, Dr. E.), 328

Pentahydroxybenzene, Derivatives of (Baker, W.), 141

Periodic System (Completion of the), Radioactivity and the (Paneth, Prof. F. A.), 565

Periodicity, of Refection in the Wild Rabbit (Southern, H. N.), 553; Seismic, 308; and Time Series, Progress Report on (Blake, Archie), 308

Permalloy, Magnetostriction in (Williams, H. J., Bozorth, R. M., and Christensen, —.), 359

Permian Fossils from the Eastern Himalaya (Wagner, Dr. L. R.), 172

Perspective Diagrams, Preparation of (Hobson, Dr. G. D.), 209

Peru, Population of, 607

Pests (Rodent) in War-time, 190

Petroleum (Search for) in Australia (Demaine, C. S.), 303; (Milner, H. B.), 303

Petroleum Industry, Evolution in the (Kewley, James), 224

Petrology and Prehistory (Keiller, A., Piggott, Stuart, and Wallis, F. S.), 275

Pharmaceutical Codex, 1934 (British), Supplement to the, Part 1: Monographs (New Monographs), *review* 593

Pharmacology and Chemotherapy, Bibliography of, 166

Phenology of 1941, 497

Phenols (Halogenized) as External Disinfectants, Chemotherapeutical Use of (Zondek, Prof. Bernhard), 334

Philippines, Earthquake on April 8, 1942, 435, 469; Fishes from the (Fowler, Henry W.), 700

Philistines, A Sling against the, the New Machinery of Government by the People (Becker, Denis), 105

Philosophy, An Individualist's, *review* by Prof. W. G. de Burgh, 315

Philosophy of the Physical Sciences, Some Disputed Questions in the (Whittaker, Prof. E. T.), 268

Philosophy and the Sciences, *review* by Dr. W. H. S. Jones, 422

Philosophy of Alfred North Whitehead (edited by Schilpp, Paul Arthur), *review* by Prof. N. Kemp Smith, 710

Phosphorus Trifluoride and Oxyfluoride (Tarbutton, G., Egan, E. P., and Frary, S. G.), 52

Phosphorylation (Decrease in Glycogen) in Muscles *in vitro* after Adrenalectomy and Restoration with Desoxycorticosterone (Verzar, Prof. F., and Montigel, C.), 49

Photo-decomposition of Acetone (Spence, R., and Wild, W.), 114

Photographic Method of Estimating the Mass of the Mesotron (Bose, Dr. D. M., and Choudhuri, Miss Bibha), 302

Photography (Role of) in the Detection and Measurement of Radiation (Davies, E. R.), 430

Photography in Science, Medicine and Industry (Association of Scientific Workers exhibition of), 498

Photosynthesis, Quantum Efficiency of (Baly, Prof. E. C. C.), 218

Physical Basis of Radiology, *review* by Prof. W. V. Mayneord, 452

Physical Instruments for the Biologist (Bronk, Detler W.), 436

Physical Science in the U.S.S.R. (Bernal, Prof. J. D.), 545

Physical Sciences, Some Disputed Questions in the Philosophy of the (Whittaker, Prof. E. T.), 268; Impact of the, on Society (Crowther, Prof. J. A.), 96

Physical Society, celebration of Newton Tercentenary, 192; Sir Edward Appleton to deliver the twenty-sixth Guthrie Lecture, 299; eighteenth Duddell Medal awarded to Dr. W. D. Coolidge, 521; inaugural meetings of the Optical Group, 324

Physical World, This (Clark, Prof. C. C., Johnson, C. A., and Cockaday, Lt.-Comdr. L. M.), *review*, 155

Physical and Chemical Constants, Tables of (Kaye, Dr. G. W. C., and Laby, Prof. T. H.), ninth edition, *review*, 453

Physicists During and After the War (Bragg, Sir Lawrence), 634

Physico-Chemical Processes (Linkage of) in Biological Systems (Conway, Prof. Edward J.), 383, *erratum*, 438; (Donnan, Prof. F. G.), 383

Physics (College), An Introductory Course in (Black, Prof. Newton Henry), revised edition, *review*, 9

Physics, Institute of, Planning Committees, 20; Conference on X-Ray Analysis in Industry, 166; Conference on Electronics, 278; Conference on X-Ray Analysis in Industry, 503; Planning Committee to consider the training and position of physicists after the War, 634; annual report of, 635; formation of an Electronics Group, 635; Sir Lawrence Bragg elected president of the Electronics Group, 635; joint meeting of the London and Home Counties' Branch with the Geological Society of London on Geophysical Methods in Geology, 690

Physics, Practical (Physics Supervisory Staff, the Pennsylvania State College), *review*, 424

Physics, Radiology (Robertson, Prof. John Kellock), *review* by Prof. W. V. Mayneord, 452

Physics, Teaching of (*a*) Fundamental Laws and Definitions (Hansel, C. W.), 460; (*b*) The Need for a Permanent Standardization and Guidance Committee for Elementary Physics (Woodland, P.), 460

Physics, University (Champion, Dr. F. C.), Part 3: Light; Part 4: Wave-Motion and Sound, *review*, 125

Physics of the Air (Humphreys, Dr. W. J.), third edition, *review*, 8

Physics for Engineers (Fleming, Sir Ambrose), *review*, 181

Physics of a Transmission Line (Thornton, Prof. W. M.), 268

Physics (Elementary) and Chemistry for Students of Biology (Woodall, Dr. E. A., and Denne, E. C.), *review*, 425

Physiology, of the Amino Acids (Van Slyke, Dr. Donald D.), 342; (Bacharach, A. L.), 473; for Pharmaceutical Students (Barber, Dr. Harold Hayden), second edition, *review* by Prof. Samson Wright, 61; Starling's Principles of Human, eighth edition, edited and revised by Prof. C. Lovatt Evans, *review* by Prof. Samson Wright, 61

Phytoplankton Productivity (Sears, Mary), 476

Piezo-Electro Crystal Filters (Benson, J. E.), 20

Pig Back Depot Fat, Relative Firmness of (Bolton, W., and Baskett, R. G.), 670

Pigs, Hæmophilia-like Conditions in (Bogart, R., and Muhrer, M. E.), 641

Pine Shoot Beetles (Ossowski, Dr. Leon), 252

Pituitary, The Amphibian (Hogben, Prof. Lancelot), 695

Place-Names of Middlesex, apart from the City of London (Gover, J. E. B., Mawer, Allen, Stenton, F. M., and Madge, S. J.), *review* by Sir Charles Peers, 370

Plan for Living, the Architect's Part (Williams-Ellis, Clough), 589

Planets and Satellites, Origin of (Lyttleton, R. A.), 114

Planisphere (The Observer's) of Air Navigation Stars (Chichester, Ft.-Lieut. Francis), *review* by Dr. H. Spencer Jones, 450

Plankton Hauls from the non-magnetic ship *Carnegie* (Graham, H. W.), 476

Planning, Overture to (Osborn, F. J.), 31; for Agricultural Production (Russell, Sir John), 318

Planning (National) Background to, 31

Planning (Post-War) in Radio Telecommunication (Institution of Electrical Engineers (Wireless Section) discussion on), 614

Planning (Town), Industry and (Pumphrey, Roland), 588

Planning (Town and Country), Legislation affecting (Report by the Reconstruction Committee of the Royal Institute of British Architects), 588

Planning Authority, Central, 214

Planning Bill (Works and), Ministry of, 521

Planning Committee (Institute of Physics), 20

Planning and Rebuilding in Britain, 496

Planning and Regional Reconstruction, Ltd., Association for, 496

Plans (Government) for Reconstruction, 298

Plant Breeding Station at Aberystwyth, Dr. T. J. Jenkin appointed professor of agriculture and director of the, 549

Plant Breeding, Indian Journal of Genetics and, volume for 1941, 325

Plant Cell, Cytoplasm of the (Guilliermond, Prof. Alexandre), translated by Dr. Lenette Rogers Atkinson, *review* by Dr. F. C. Steward, 484

Plant Collectors, Two Early, 438

Plant Metabolism, Heavy Carbon Isotope in, (Belkengren, R., Nier, A. O., and Burr, G. O.), 24

Plant Ontogeny, A Study in (Burkill, I. H.), 387
Plant Science Formulæ (McLean, Prof. R. C., and Cook, Dr. W. R. Ivimey), *review*, 150
Plant Viruses, Crystallography and (Bawden, F. C.), 321
Plants and Animals, Rapid Determination of Water in (Lowndes, A. G.), 79
Plastic Deformation (A Type of) New in Metals (Orowan, Dr. E.), 643
Plastics, The Toughness, Strength and Flexibility of (Baker, W. O.), 504; in Industry ("Plastes"), second edition, *review* by Dr. E. F. Armstrong, 682
Platinum Medal of the Institute of Metals, awarded to W. Murray Morrison, 135
Pleistocene Climates in Kenya and Abyssinia (Kent, P. E.,) 736
Pleistocene Raised Beaches on the West Coast of Morocco (Breuil, Abbé H.), 77
Plymouth and at Hull, Nitzschia Cultures at (Wilson, D. P., and Lucas, C. E.), 331
Podsols in Uganda, Lowland Tropical (Thomas, A. S.), 195
Poisons (Industrial), Hazards and Solvents, The Analytical Chemistry of (Jacobs, Dr. Morris B.), *review*, 179
Polarization of the Corona (Allen, G. W.), 53
Poles, Lodgewood Telegraph (Amadon, C. H.), 467
Political Remodelling (Ethical and) of Society (Kenyon, Sir Frederic), 100
Politics, Relation of Science to, 253
Politics (International) Science and (Gregory, Sir Richard), 261
Pollen in a Pear, A Useful Abnormality of the (Thomas, Dr. P. T.), 168
Polygene Concept (Mather, Dr. K.), 731; ('Espinasse, Dr. Paul G.), 731
Polygenic Inheritance and the Drosophila Culture (Gordon, Dr. C., and Sang, J. H.), 610
Polymeric Reactions, High (Mark, Prof. H., and Raff, R.), *review* by Prof. H. W. Melville, 260
Polyploid Forms of Brassica and Raphanus, Self-incompatibility in (Howard, Dr. W. H.), 302
Polysaccharides (Bacterial), Enzymatic Production of (Stacey, Dr. M.), 639
Population, of Peru, 607; of Sweden, 382
Population (Density of) of the Pink Salmon (Davidson, F. A., and Vaughan, Elizabeth), 476
Population (Large), Accuracy of a Few Observations in a (Stevens, W. L.), 700
Population Problems, Health Services and, 707; Social Science, Statistics and (Jones, D. Caradog), 98
Population Trends in India, Half a Century of (Geddes, A.), 304
Post-War Agricultural Reconstruction (Jacks, G. V.), 372
Post-War Europe, Feeding (Bourne, Dr. Geoffrey), 182, *erratum*, 217
Post-War Needs, World Mineral Resources and, 576
Post-War Planning in Radio Telecommunication (Institution of Electrical Engineers (Wireless Section) discussion on), 614
Post-War Problems, Scientific Societies and, 73
Post-War Reconstruction, Nature Preservation in, 2; Town and Country Planning Association meetings on, 20
Post-War Schools, Science in (Savage, E. P.), 459; (Brown, S. V.), 459
Post-War World (The Coming), Association of Scientific Workers (Rugby Branch) lectures on, 136
Post-War Zoos, 74
Potable Water from Sea-Water (Parker, Dr. A.), 184, 357; (Yapp, W. B.), 357
Potassium (Isotopic Shift of) in Human Bone-marrow and Cancer (Lasnitzki, Dr. A., and Brewer, Dr. A. K.), 357
Potassium, Silver and Bromine, Atomic Weights of (McAlpine, R. K., and Bird, E. J.), 305
Potato in India, The (Kidd, Dr. Franklin), 199
Potato (Indian), Cold Storage of the (Karmarkar, Dr. D. V., and Joshi, B. M.), 199
'Potato-sickness', Trace-elements and (Ellenby, Dr. C.), 50
Potato Virus, A New Strain of (Clinch, Phyllis M.), 249
Potatoes, Genetic Nature of Self- and Cross-Incompatibility in (Pal, Dr. B. P., and Nath, Dr. Pushkar), 246
Pottery-making in Nanyikaland (Martin, C.), 225
Poulkovo Observatory, destruction of, 297
Poverty and Malnutrition in South Africa, Remedies for (Osborn, Dr. T. W. B.), 18
Power (Electric) Stations (Carr, T. H.), Vol. 2, *review*, 371
Power Supply Systems, Circuit-controlling Devices on (Marshall, C. W.), 673; Protective Gear on (Casson, W., and Birch, F. H.), 165
Practice (Science and) in Agriculture, 722
Precision Measurements, An Improved Capacitance Bridge for (Voelker, W. D.), 468
Predictive Method in Animal Ecology (Maclagan, Dr. D. Stewart), 115
Pregnant and Non-pregnant Cows, Rheological Properties of Secretions from the Cervix of (Blair, Dr. G. W. Scott, Cowie, A. T., and Coppen, F. M. V.), 609
Prehistoric Artefacts (Ground and Polished) from Ceylon (Deraniyagala, P. E. P.), 384
Prehistory (de Pradenne, Prof. A. Vayson), *review* by M. C. Burkitt, 232; and European Civilization (Hawkes, C. F. C.), 427; Petrology and (Keiller, A., Piggott, Stuart, and Wallis, F. S.), 275; South African (Burkitt, M.C.), 225
Premises, Electric Heating of (Gilchrist, W.), 408
Preservation, of Iron by Paint, Laboratory Test for (Gibney R. B.), 250; of Ornamental Trees, *review* by Fraser Story, 314; of Stored Wheat in Australia, 165
Press, Science and the (Carr, C. F.), 617
Prevention of Blindness, 665
Primitive Scenes and Festivals (Sitwell, Sacheverell), *review* by Prof. R. M. Dawkins, 714
Prisoners of War (British Zoologist) in Europe (Griffin, Francis J.), 248
Problem of the Autonomy of Life, *review* by Prof. F. G. Donnan, 394, 551; (Kapp, Prof. Reginald O.), 551; (Beadnell, Surgeon Rear-Admiral Charles M.), 551
Production, Organization of, 507; Statistical Control of (Darwin Dr. C. G.), 573; and Hours of Work, 281
Production (Enzymatic) of Bacterial Polysaccharides (Stacey, Dr. M.), 639
Proliferation-Promoting Factors (Activity of) from Injured Cells, Relation of Aeration to the (Loufbourow, Prof. John R., Webb, Dr. Alfred M., and Abramowitz, Rosaline K.), 272
Properties of Rubber at Low Temperatures, 645
Prosecution, Science for the (Grant, Dr. Julius), *review* by Dr. J. Davidson, 536
Prospects (Human), Science and (Blackwelder, Prof. Eliot), *review* by F. S. Marvin, 623
Protective Gear on Power Supply Systems (Casson, W., and Birch, F. H.), 165
Protective Structures (Design of) and the Defence of Industry (Baker, Prof. J. F.), 673
Proteins Susceptible to Cold in Pathological Sera (Stein, L., and Wertheimer, Dr. E.), 528
Proteins (Genes, Viruses and), 242
Proteins and other Nutrients, Green Leaves as a Source of (Pirie, N. W.), 251
Protozoa in Biology Research (edited by Calkins, Gary N., and Summers, Francis M.), *review* by Clifford Dobell, 149
Protozoology in the United States, *review* by Clifford Dobell, 149
Psycho-Analysis, Logical Foundations of, *review* by Dr. John Cohen, 563
Psychoanalytical Method and the Doctrine of Freud (Dalbiez, Dr. Roland), *review* by Dr. John Cohen, 563
Psychological Aspects of English Social Stratification (Pear, Prof. T. H.), 487
Psychological Society (British), symposium on Social Stratification, 487; discussion on Quantitative and Qualitative Method in Sociological Research, 516
Psychology, of Evacuation, *review* by Dr. A. W. Wolters, 152; of Hate (Fromm, Dr. Erich), 728; of C. G. Jung (Jacobi, Dr. Jolan), *review* by Dr. Clifford Allen, 622
Psychology, Child (edited by Skinner, Charles E., and Harriman, Philip Lawrence), *review* by T. Raymont, 204; A Mystical, *review* by Dr. Clifford Allen, 622
Psycho-Physical Significance of the Dissipation Coefficient of Soft Materials (Blair, Dr. G. W. Scott, and Coppen, F. M. V.), 22

Pterins, Chemistry of (Hopkins, Sir Frederick Gowland), 359
Public Address Systems (Hill, S.), 381
Public Health, in India, 191; in the United States, 46
Purity and Fine Measurement, *review* by Prof. A. C. Egerton, 229

QUALITATIVE (Quantitative and) Method in Sociological Research (British Psychological Society discussion on), 516
Quality Control in Manufacture (Rissik, H.), 408; (Dudding, Bernard P.), 555
Quantitative and Qualitative Method in Sociological Research (British Psychological Society discussion on), 516
Quantum Chemistry, 642
Quantum Efficiency of Photosynthesis (Baly, Prof. E. C. C.), 218
Quantum Theory and Diffuse X-Ray Reflexions (Preston, G. D.), 373; (Born, Prof. Max, Lonsdale, Dr. Kathleen, and Smith, H.), 402
Quekett Microscopical Club, election of officers, 409
Quenching (Reversible) by Oxygen of the Fluorescence of Polycyclic Hydrocarbons (Weil-Malherbe, Dr. H., and Weiss, Dr. Joseph), 471, 612; (Bowen, E. J.), 528
Quetta, Earthquake of December 20, 1941, 20

RABBIT, Linkage Studies in the (Castle, W. E., and Sawin, P. B.), 276; Periodicity of Refection in the Wild (Southern, H. N.,) 553
Rabbit Eggs, Parthenogenetic Activation of (Shapiro, Herbert), 304
Rabbit Population of Great Britain, Control of the (Middleton, A. D.), 190
Race, Disease and (Gorer, Dr. P. A.), 426; and Fascism, 426; The Meaning of (Morant, Dr. G. M.), 426; Nationality and Class (Torr, Miss Dona), 427
Race Relations, Sociological Research in (Little, K. L.), 196
Racial Theories and Biological Fact (Haldane, Prof. J. B. S.), 426
Racialism, Fallacies of, *review* by Prof. H. J. Fleure, 590
Racialism against Civilization (Zollschan, Dr. J.), *review* by Prof. H. J. Fleure, 590
Radiation (Detection and Measurement of), Role of Photography in the (Davies, E. R.), 430
Radiation (Downward) of the Earth's Atmosphere (Narayanaswami, R.), 279
Radiation (Measurement of) for Medical Purposes (Mayneord, Prof. W. V.), 600
Radio Communication, The Future of (Eckersley, Capt. P. P.), 465
Radio Receiver Design, 191
Radio Research and the War (Bailey, C. E. G.), 617
Radio Telecommunication, Post-War Planning in (Institution of Electrical Engineers (Wireless Section) discussion on), 614
Radioactivity and the Completion of the Periodic System (Paneth, Prof. F. A.), 565
Radiology, Physical Basis of, *review* by Prof. W. V. Mayneord, 452
Radiology Physics (Robertson, Prof. John Kellock), *review* by Prof. W. V. Mayneord, 452
Radiotherapeutic Research Unit of the Medical Research Council, 216
R.A.F. Bomber, New, 165
Railway Oil Engine, Future of the (Reed, B.), 378
Rain (Cloud and), Electricity of (Chalmers, Dr. J. Alan), 659; (Simpson, Sir George), 659
Rainbow Bridge over the Niagara Falls, 326
Rainfall, Forecasting Monsoon (Iyer, V. Doraiswamy, and Seshachar, C.), 280; North-east Monsoon, of the South of Madras (Iyer, V. Doraiswamy), 670
Rainfall Flooding and Health (Graham, D. C.), 435
Raman's Theory of Specific Heat of Crystals (George, Dr. W. H.), 540
Ramanujan, Srinivasa (Neville, Prof. E. H.), 292
Random Element in Time Series, *review* by M. G. Kendall, 369
Raphanus (Brassica and), Self-incompatibility in Polyploid Forms of (Howard, Dr. H. W.), 302
Rat Control (Hardy, Eric), 190
Rate Processes, The Theory of (Glasstone, Samuel, Laidler, Keith J., and Eyring, Henry), *review* by Prof. M. Polanyi, 509
Rationalist, Why I am a, Books which have Influenced Me, 665
Rats (Bacteria and), 2-Aminofluorene as Growth Inhibitor for (Bielschowsky, F., and Green, Prof. H. N.), 526, *erratum*, 607
Rats (Vitamin A-Deficient), Absorption of Minimal Doses of β-Carotene by (Ramasarma, G. B., and Hakim, D. N.), 611
Raw Materials in the New World Community (Mather, Prof. Kirtley F.), 377
Ray Society, report of the Council, 606
Rays and their Allies from the Eastern Pacific (Beebe, William, and Tee Van, John), 113
Rebuilding (Planning and) in Britain, 496
Reconstruction, The Basis of (Bowie, Dr. J. A.), 337; and the Building Industry, 419; in China (Kuo, Zing Yang), 42; Colonial Development and, 365; and Economics, 117; Government Plans for, 298; International Aspects of, 201; Labour and Management in, 559; and the Land, an Approach to Farming in the National Interest (Hall, Sir A. Daniel), 13; and Peace ("Balbus"), 338; Post-War Agricultural (Jacks, G. V.), 372; Smoke Abatement and, 477; of World Trade (Condliffe, Prof. J. B.), 202, 311
Reconstruction, Ltd. (Planning and Regional), Association for, 496
Reconstruction Associations, British (P.E.P. Broadsheet), 521
Reconstruction (World), Leadership in, 337
Reducing Substances (Volatile) in Vinegars (Whitmarsh, J. M.), 332
Refection (Periodicity of) in the Wild Rabbit (Southern, H. N.), 553
Reflexion from Paper (Burke, E.), 613; (Harrison, Dr. V. G. W.), 613; (Strachan, J.), 732; (Bowen, J. Leonard), 733; (King, Dr. J. Leycester), 733
Reflexions (Extra) of X-Rays from Diamond (Lonsdale, Dr. Kathleen), 671
Refraction (Conical), Optical Images formed by (Raman, Sir C. V., and Nedungadi, T. M. K.), 552
Refrigeration ('Deep'), Carl von Linde, a Pioneer of (Awbery, J. H.), 630
Regional Propositions for Tyneside, 105
Registers, The Central and Supplementary, 496
Relationship ?, Domination or, *review* by H. G. Baynes, 203
Relaxation Methods in Engineering Science (Southwell, Prof. R. V.), *review* by Prof. G. Temple, 123
Relict Adaptation, Degeneration and (Huxley, Prof. Julian), 687
Remodelling (Ethical and Political) of Society (Kenyon, Sir Frederic), 100
Rennet Coagulation, The Second Phase of (Berridge, N. J.), 194
Replanning Britain, being a Summarized Report of the Oxford Conference of the Town and Country Planning Association, 31
Replanning Great Britain, 587
Reproduction (Heterothallism and) in Fungi (Madge, Dr. Margaret A. P., and Blackwell, Elizabeth), 440
Reptiles (Captorhinomorph), Ancestry of (Westoll, Dr. T. S.), 667
Research, in Agriculture (Walton, Dr. A.), 209; on Electrical Surges, *review* by Dr. T. E. Allibone, 621; in the Social Sciences, The Case for (Catlin, Prof. George E. G.), 88; in the History of Sociology (Farquharson, Alexander), 101
Research (Centralized) in the Social Sciences, 88
Research (Economic and Social), National Institute of, 416
Research (Fuel), Development of (Smith, Dr. E. W.), 466
Research (Grassland) in Great Britain, 549
Research (Low-Temperature) and Development in the Soviet Union (Ruhemann, Dr. M.), 546
Research (Meteorological) in Great Britain, 544
Research (Radio) and the War (Bailey, C. E. G.), 617
Research (Recent) in Oceanography (Deacon, Dr. G. E. R.), 476

Research (Scientific), Anglo-American Co-operation in (Conant, President James B.), 10; in Sweden, 407
Research (Scientific) and Development in the Empire (Hill, Prof. A. V.), 653
Research (Scientific and Industrial), in Canada, 80
Research (Sociological), Quantitative and Qualitative Method in (British Psychological Society discussion on), 516
Research (Statistics in), Utilization of, *review* by M. G. Kendall, 451
Research and Statistical Methodology, The Second Yearbook of (edited by Buros), Oscar Krisen, *review*, 9
Research Grants of the American Philosophical Society, 694
Research Workers, Statistical Methods for (Fisher, Prof. R. A.), eighth edition, *review* by M. G. Kendall, 451
Resistance and its Mechanism, Hormonal Increase of (Agduhr, Prof. Erik), 171
Resistance to Toxic Substances of Mutants of Drosophila of Different Body Colour, Difference in (Kalmus, Dr. H., Martin, Dr. J. T., and Potter, C.), 110
Respiration and the Assimilation of Carbon Dioxide, 29
Respiration in Barley (James, W. O., and Bunting, —), 222
Respiratory Organ, The Tail of a Fish Larva as (Sawaya, Prof. Paulo), 169
Restaurants (British), The Function of, 675
Revolution, A Social, *review* by F. S. Marvin, 623
Reynolds (Osborne) Medal of the Institution of Chemical Engineers, awarded to Dr. A. Parker, 409
Rheological Properties, Classification of (British Rheologists' Club discussion on), 197, 702
Rheological Properties of Secretions from the Cervix of Pregnant and Non-pregnant Cows (Blair, Dr. G. W. Scott, Cowie, A. T., and Coppen, F. M. V.), 609
Rheologists' Club (British) discussion on the Classification of Rheological Properties, 197, 702
Rhesus Monkey (*Macaca mulatta*), Embryology of the, *review* by Dr. S. Zuckerman, 592
Rhodesia, Incomes in (Shaul, J. R. H.), 275; Meteorology of, 269; Rock-shelter Paintings of Southern (Cripps, Hon. L.), 225
Rhubarb (Seakale, Artichoke, Sweet Corn, Asparagus, and), Uncommon Diseases of (Green, D. E.), 641
Riboflavin in Cereals, Microbiological Assay of (Barton-Wright, Dr. E.), 696
Rio de Janeiro, Demographic Census of, 523
Rock-shelter Paintings of Southern Rhodesia (Cripps, Hon. L.), 225
Rockefeller Foundation, grant to the Royal Society, 270
Rockefeller Medical Studentships, 243
Rocksalt, Crystal Dynamics of (Lonsdale, Dr. Kathleen), 698
Rodent Pests in War-time, 190
Romanticism (German), Natural Science in (Aesch, Alexander Gode-von), *review* by Prof. A. Wolf, 104
Romanticism and Science, *review* by Prof. A. Wolf, 104
Röntgen Radiation, Modification of Injury Produced by (Evans, T. C.), 24
Roses, Origins of (Hurst, C. C.), 249
Rossi Curve, The Second Maximum in the (Mohr, Dr. C. B. O., and Stafford, G. H.), 385
Rotation of the Milky Way, 74
Royal Academy, 1942, Science and Art at the (Hopwood, Dr. A. T.), 603
Royal Institution, special arrangements for carrying on the work of the, 693
Royal Society, New Fellows of the, 351; U.S.S.R. Academy of Sciences and the, 663; Celebration of the tercentenary of the birth of Sir Isaac Newton, 635; Lord Hankey elected a Fellow under Statute 12, 726; New Foreign Members of, 726; Croonian Lecture by Hogben, Prof. L., 735
Royal Society of Arts, Thomas Gray Memorial Trust Prize awarded to T. E. Metcalfe, 270
Royal Society of Edinburgh, elections to, 267; Keith Prize for 1939–41 awarded to Prof. E. T. Copson and Prof. W. H. McCrea, 268; Neill Prize for 1939–41 awarded to Dr. P. C. Koller and Dr. W. J. McCallien, 268; Year Book for 1940–41, 438
Royal Society of South Africa, election of officers, 607
Rubber, at a Turning Point? *review*, 452; and its Use (Fisher, Harry L.), *review*, 452; Brittle Temperature of (Selker, M. L.), 645; Properties of, at Low Temperatures, 645
Rubber (Synthetic), in the United States, 75; Production in Canada, 327
Rumen Microflora (Normal) and Microfauna of Cattle (Baker, Frank), 220
Rural Life (Industry and), Conference on (Town and Country Planning Association), 354
Russia and the Ukraine, Collective Farming in (Roberts, Dr. E. J.), 705; (Russell, Sir John), 705
Russian for Scientific Workers (Russell, Sir John), 502
Russian Controversy, Genetics and the (Mather, Dr. K.), 427

ST. ANDREWS, University of (Regional Committee for Adult Education of the), publication of pamphlets under the general title "Scotland and its People", 605
Sailfish, Young Pacific (Beebe, William), 113
Salmon of the Owenduff (Ballycroy) River (Went, A. W. E. J.), 52
Salmon (Pink), Density of Population of the (Davidson, F. A., and Vaughan, Elizabeth), 476
Salmon Gill Maggots (Friend, G. F.), 414
Salmonella Type, A New (Monteverde, Dr. J. J.), 472, *erratum*, 498
Santa Barbara, California, Earthquake on June 30, 1941, 299
Sargasso Sea, The (Deacon, G. E. R.), 332
Scattering of Neutrons in Deuterium (Sundarachar, Prof. C. K., and Streib, Dr. J. F.), 51
Scenes (Primitive) and Festivals (Sitwell, Sacheverell), *review* by Prof. R. M. Dawkins, 714
Scenic Approach to Meteorology (Bonacina, L. C. W.), 326
Scholarships, Agricultural (Ministry of Agriculture and Fisheries), 469; in Electrical Engineering (Institution of Electrical Engineers), 270
School Medical Service in War-time (Glover, Dr. J. Alison), 550
Schools (Post-War), Science in (Savage, E. G.), 459; (Brown, S. V.), 459
Science, The Advancement of, No. 5, 189
Science, Board of Education scheme of State bursaries in, 108; Elementary General (edited by Harrison, J. M.), Book 3, *review*, 424; An Experiment in Social, 143; Forensic, *review* by Dr. J. Davidson, 536; Two Eminent German Men of, 727; An Historical Survey of the Rise of (Taylor, Dr. F. Sherwood), 515; Individuality and (Blakeslee, Dr. A. F.), 288; The Nazi Attack on International (Needham, Dr. Joseph), 215; Nazism and, 215; in Post-War Schools (Savage, E. G.), 459; (Brown, S. V.), 459; for the Prosecution (Grant, Dr. Julius), *review* by Dr. J. Davidson, 536; Romanticism and, *review* by Prof. A. Wolf, 104; The Teaching of, 161; Physical, in the U.S.S.R. (Bernal, Prof. J. D.), 545; The History of, in Scotland (Thompson, Sir D'Arcy), 605; in Soviet School Education (King, Mrs. Beatrice), 547; Lifts the Veil (Bragg, Sir William), 108; for Victory (Association of Scientific Workers, Southern Area Committee, Conference on), 616
Science Course, English in the (Lyon, Hugh), 454
Science Masters' Association, Forty-first annual meeting, 299, 456; presidential address on English in the Science Course (Lyon, Hugh), 455
Science Teaching, Science and (Harris, E. T.), 734
Science and Art at the Royal Academy, 1942 (Hopwood, Dr. A. T.), 603
Science and Citizenship Foundation, second lecture to be given by Prof. Lancelot Hogben, 354
Science and the Classics, 134
Science in Education, The Place of (de Ternant, Rev. Philip), 516
Science and Engineering in China, 693
Science and Ethics, a Hindu View (Gundappa, D. V.), 433
Science as a Force of Freedom (Lal, G. B.), 268
Science (Modern) and Thomas Hobbes (Bell, A. E.), 688
Science and Human Prospects (Blackwelder, Prof. Eliot), *review* by F. S. Marvin, 623

Science and International Politics (Gregory, Sir Richard), 261
Science and Man (Newsholme, Dr. H. P.), 516
Science versus Materialism (Kapp, Prof. Reginald O.), *review* by Prof. F. G. Donnan, 394
Science (Historical Medicine and), Schuman's catalogue of books on, 498
Science (Modern) and Musical Theory (Lloyd, Ll. S.), 389
Science to Politics, Relation of, 253
Science and Practice in Agriculture, 722
Science and the Press (Carr, C. F.), 617
Science and Science Teaching (Harris, E. T.), 734
Science and Scientific Workers in the War, Use of, 130
Science and Society, 85; (Taylor, Dr. F. Sherwood), 515
Science and Technology in the Soviet Union (Marx Memorial Library and Workers' School Symposium on), 327, 545
Science and War (Clark, Austin H.), 570
Science and the War Effort (Association of Scientific Workers Conference on), 71, 130, 161, 208, 616
Science (The Application of) to the War Effort in Milk Production and Utilization (Kay, Prof. H. D.), 208
Science and World Order, 189
Sciences (Biological) in the U.S.S.R. (Haldane, Prof. J. B. S.), 546
Sciences, Philosophy and the, *review* by Dr. W. H. S. Jones, 422
Sciences, The Social (Catlin, Prof. George), 524
Scientific Advisory Council, Jerusalem, 438
Scientific Advisory and Engineering Advisory Committees, R. A. Butler to be chairman of the, 327
Scientific Aids for the Layman, *review* by T. Raymont, 713
Scientific Attitude to Fascism, with particular reference to Racial Theories (Marx Memorial Library and Workers' School Symposium on), 327, 426
Scientific Child-Study, *review* by T. Raymont, 204
Scientific Committee (Parliamentary and), first annual luncheon, 164
Scientific Co-operation between Great Britain and the U.S.S.R., 297
Scientific Direction of War, 549
Scientific Film and Scientific Film Societies (Association of Scientific Workers' Conference on the), 729
Scientific Food Policy, 309
Scientific Help for the Home Guard (Langdon-Davies, Capt. John), 79
Scientific Information (Exchange of) with the U.S.S.R., 663
Scientific Invention at the Service of the Community (Langdon-Davies, Capt. John), 298
Scientific Knowledge among British Farmers, The Better Dissemination of (Parliamentary and Scientific Committee discussion on), 722
Scientific Research in Sweden, 407
Scientific Societies and Post-War Problems, 73
Scientific Studies, Stalin Prizes for, 475
Scientific Study of Society (Mess, Dr. Henry A.), 624
Scientific Terms (Dictionary of), as used in the Various Sciences (Beadnell, Surgeon Rear-Admiral C. M.), second edition, *review* by T. Raymont, 713
Scientific Utilization of Man-power, 531
Scientific Work of Elie Metchnikoff (Petrie, Dr. G. F.), 547
Scientific Worker in Soviet Society (Ruhemann, Dr. M.), 547
Scientific Workers, of the Argentine, 576; (Austrian) in Great Britain, 577; Hospitality in Australia for (Carne, Dr. L. H. R.), 17, 23; Russian for (Russell, Sir John), 502; Use of Science and, in the War, 130
Scientific Workers, Association of, Message to American men of science, 17; Conference on Science and the War Effort, 71, 130, 161, 208, 616; (Rugby Branch) Lectures on the Coming Post-War World, 136; Annual Council Meeting, 469, 550; Committee to help foreign men of science in Great Britain, 498; Exhibition of photography in Science, Medicine and Industry, 498; Science for Victory Conference, 616; Conference on the Scientific Film and Scientific Film Societies, 729
Scotland, Health of, 74; The History of Science in (Thompson, Sir D'Arcy), 605; Industry in, 577
Scotland and its People (Regional Committee for Adult Education of the University of St. Andrews), publication of pamphlets under the general title of, 605
Scotland (North-east), Sheep Strike by the Fly, *Phormia terrae-novae* R.-D., in (Morison, Dr. G. D.), 358
Scott (John) Medals and Premiums of the American Philosophical Society awarded to Armstrong, Major Edwin H., and Williams, Robert R., 243
Sea and Inland Fisheries, Irish, report of the Minister of Agriculture (Eire) for 1940, 605
Seakale, Artichoke, Sweet Corn, Asparagus and Rhubarb, Uncommon diseases of (Green, D. E.), 641
Sea-Water, Potable Water from (Parker, Dr. A.), 184, 357; (Yapp, W. B.), 357
Sea-Waves, their Growth and Subsidence (Unna, P. J. H.), 584
Seaweed as a Food for Livestock (Beharrell, J.), 306
Secretions (Rheological Properties of) from the Cervix of Pregnant and Non-pregnant Cows (Blair, Dr. G. W. Scott, Cowie, A. T., and Coppen, F. M. V.), 609
Sedimentation of Washed Red Blood Cells (Whittington, R. B.), 305
Seed Germination (Linnean Society discussion on), 658
Seed Production Committee of the National Institute of Agricultural Botany, 299
Seismic Periodicity, 308
Seismic Surveying in New England, 380
Seismograph Station (The Oldham) at Utah State Agricultural College, Logan, Utah (Williams, J. Stewart), 585
Seismological (International) Summary (Bellamy, Miss E. F.), 380
Seismology, Bibliography of, July–December 1941 (Hodgson, Ernest A.), 665; in the South-western Pacific, 243
Self-Analysis, A Practical Method of (Farrow, Dr. E. Pickworth), *review* by Dr. Millais Culpin, 713
Self-Incompatibility (Breakdown of) by α-Naphthalene Acetamide (Lewis, D.), 610
Self-Incompatibility in Polyploid Forms of Brassica and Raphanus (Howard, Dr. H. W.), 302
Self- and Cross-Incompatibility in Potatoes, Genetic Nature of (Pal, Dr. B. P., and Nath, Dr. Pushkar), 246
Semitism (Anti-) from the 'materialist' point of view (Levy, Prof. H.), 427
Sentimental Journey, A, *review* by Prof. J. L. Myres, 449
Separation of Isotopes (Thode, H. G., and Walkling, F. O.), 700
Sera (Pathological), Proteins Susceptible to Cold in (Stein, L., and Wertheimer, Dr. E.), 528
Serum (Human), Behaviour of Lipoids in (McFarlane, Dr. Arthur S.), 439
Services, Skilled Man-Power in the, 255
Sex Ratio (Temperature and) in *Drosophila pseudo-obscura* (Darlington, C. D., and Dobzhansky, Th.), 670
Sexual Characters (Secondary) of Tribolium (Hinton, H. E.), 500
Shearwaters (Lockley, R. M.), *review* by Seton Gordon, 284
Sheep Farming, Hill, 108
Sheep Strike by the Fly, *Phormia terrae-novae* R.-D., in North-east Scotland (Morison, Dr. G. D.), 358
Sheffield, University of, bequest by the late L. N. Ledingham, 217; Thirty-sixth annual report of the Senate, 45
Shock (Nervous) in Peace and War (Brend, Dr. William A.), 324
Shoot Apex in Grasses and Cereals (Sharman, Dr. B. C.), 82
Short 'Stirling' Bomber of the R.A.F., 165
Sikkim (North), Upper Palaeozoic Faunas of (Muir-Wood, Helen M., and Oakley, Kenneth P.), 172
Silica (Vitreous), Structure of (Rooksby, H. P., and Thomas, L. A.), 273
Silica and the Liesegang Phenomenon (Copisarow, Alcon C., and Copisarow, Dr. Maurice), 413
Silver, Bromide and Potassium, Atomic Weights of (McAlpine, R. K., and Bird, E. J.), 305
Silver Leaf Disease (Ministry of Agriculture Advisory Leaflet No. 246), 635
Sipunculids and Echiurids of the John Murray Expedition to the Red Sea and Indian Ocean, 1933–34 (Stephen, A. C.), 57
Sky (The Night) in February, 136; in March, 243, *erratum*, 327; in April, 354; in May, 469; in June, 607; in July, 729; Spectrophotometry of the (Babcock, H. W., and Johnson, J. J.), 114
Sludge (Activated), Vorticella as an Indicator Organism for (Reynoldson, T. B.), 609

Smithsonian Institution, report for the year ended June 30, 1941, 326
Smoke Abatement and Reconstruction, 477
Snobbery (Influence of) on the Practice of Medicine (Jones, Dr. W. H. S.), 529
Snowflake Replicas for Studying Winter Storms, Use of (Schaefer, Vincent J.), 81
Soap Bubble, Time of Collapse of a (Sibaiya, Dr. L.), 527
Social Activities, Scientific Organization of, 119
Social Activity, Adult Education as a, 391
Social Hygiene Council (British), courses in biology for teachers, 192
Social Implications of Dietetics (Mottram, Prof. V. H.), 269
Social Reporting, *review*, 711
Social (Economic and) Research, National Institute of, 416
Social Revolution, A, *review* by F. S. Marvin, 623
Social Science, Biology as a (Neville-Rolfe, Mrs. S.), 90; (Brimble, L. J. F.), 457; An Experiment in, 143; Statistics and Population Problems (Jones, D. Caradog), 98
Social Sciences, The (Catlin, Prof. George), 524; British Association and, 165; The Case for Research in (Catlin, Prof. George), 88; Centralized Research in, 88
Social Stratification (British Psychological Society symposium on), 487
Social Stratification (English), Psychological Aspects of (Pear, Prof. T. H.), 487
Social Survey, Wartime, 215, 393
Sociedad Argentina de Biologia; Prof. C. Lovatt Evans elected an honorary member of, 166
Society, Ethical and Political Remodelling of (Kenyon, Sir Frederic), 100; Impact of the Physical Sciences on (Crowther, Prof. J. A.), 96; Science and, 85; (Taylor, Dr. F. Sherwood), 515; Scientific Study of (Mess, Dr. Henry A.), 624; Technology and, the Influence of Machines in the United States (Rosen, S. McKee, and Rosen, Laura), *review* by D. Caradog Jones, 63; The Old World and the New, a Report on the Problems of War and Peace Reconstruction (Labour Party), 559
Sociological Research, Quantitative and Qualitative Method in (British Psychological Society discussion on), 516; in Race Relations (Little, K. L.), 196
Sociology, Research in the History of (Farquharson, Alexander), 101
Sociology of Medicine, *review* by Dr. Joseph Geoghegan, 233
Sodium Arsenites (Nelson, O. A.), 25
Sodium Hydride (Molecular) in Interstellar Space (Pankhurst, R. C., and Pearse, Dr. R. W. B.), 612
Soil, Sons of the, Studies of the Indian Cultivator (edited by Burns, Dr. W.), *review*, 510
Soil Fertilizers in China, Use of (Chang, N. F., and Richardson, Dr. H. L.), 410
Soil Protozoa, Toxic Effects of Certain Bacterial Metabolic Products on (Singh, Dr. B. N.), 168
Soils (C/N Ratio of), Influence of Temperature and *p*H on the (Dhar, Prof. N. R., and Pant, N. N.), 83
Soils (Water in), Determination of (Locket, G. H., and Barrett, W. H.), 612
Solar Corona, The (Saha, Prof. M. N.), 524
Solar Eclipse (Total), Ionospheric Measurements during (Higgs, A. J.), 701
Solar Parallax and the Mass of the Moon (Jones, Dr. H. Spencer), 333
Solar Radiation and Atmospheric Temperature (Arctowski, Dr. H.), 276
Solar System, Meteorites and the Age of the (Arrol, W. J., Jacobi, R. B., and Paneth, Prof. F. A.), 235; Origin of the (Jeans, Sir James), 695
Solutions (Colloidal Graphite), Uses of, 298
Solvent Effect and Dipole Moments (Audsley, A., and Goss, F. R.), 276
Solvents, The Analytical Chemistry of Industrial Poisons, Hazards and (Jacobs, Dr. Morris B.), *review*, 179
Somatoplastic Sterility (Brink, R. A., and Cooper, D. C.), 141
Sons of the Soil, Studies of the Indian Cultivator (edited by Burns, Dr. W.), *review*, 510
South Africa, Poverty and Malnutrition in, 18
South African Prehistory (Burkitt, M. C.), 225
Souvenirs et travaux d'un chimiste (Pictet, Amé), *review* by Dr. Harold King, 712
Soviet Developments in Chemical Engineering (Rose, H.), 546
Soviet Economy, Geology in (Henry, Dr. N. F. M.), 546; and the War (Dobb, Maurice), *review* by R. Brightman, 681
Soviet Metallurgy (Faculty of Science, Marx House, discussion on), 578
Soviet School Education, Science in (King, Mrs. Beatrice), 547
Soviet Society, The Scientific Worker in (Ruhemann, Dr. M.), 547
Soviet Union, Electrification in the (Vowles, H. P.), 546; Low-temperature Research and Development in the (Ruhemann, Dr. M.), 546; Science and Technology in the (Marx Memorial Library and Workers' School symposium on), 327, 545
Soya-Bean Meal and Cereal Fillers, Analytical Data of (Illing, E. T., and Whittle, E. G.), 641
Space (Higher), Intuition and (Randall, M., and Longtin, B.), 114
Space (Interstellar), Molecular Sodium Hydride in (Pankhurst, R. C., and Pearse, Dr. R. W. B.), 612
Space-Charge and Electron Beams (Petrie, D. P. R.), 671
Space-heating (Electrical) Methods (Grierson, R.), 381
Spark, The Electric (Meek, J. M.), 360
Special Libraries and Information Bureaux, Association of, Sixteenth Annual General Meeting, 47
Speciation, Genetics of, *review* by Dr. K. Mather, 152
Species, Genetics and the Origin of (Dobzhansky, Prof. Theodosius), second edition, *review* by Dr. K. Mather, 152
Specific Heat of Crystals, Raman's Theory of (George, Dr. W. H.), 540
Spectra of Long-Period Variable Stars (Merrill, Paul W.), *review*, 155
Spectra (Absorption) of Unsaturated Ketones (Evans, L. K., and Gillam, A. E.), 333
Spectra (Fluorescent Lipoidal) of Human Tissue (Penn, Dr. H. S.), 193
Spectra (Mass) and Isotopes (Aston, Dr. F. W.), second edition, *review* by Prof. James Kendall, 680
Spectral Types, Galactic Absorption and Apparent Distribution of (Alter, George), 360
Spectrographic Observations (New) of Peculiar Stars (Struve, O., and Swings, P.), 80
Spectrophotometry of the Night Sky (Babcock, H. W., and Johnson, J. J.), 114
Spectroscopy and its Applications (Conference by the Optical Society of America and the Massachusetts Institute of Technology), 665
Spheres, Open Packing of (Melmore, Sidney), 412, 669
Spiders, The Comity of (Bristowe, Dr. William Syer), Vol. 2, *review* by T. H. Savory, 258
Spore Dispersal in the Mucorales (Dobbs, Dr. C. G.), 583
Sprays (Insecticidal), Biological Assay of (Parkin, Dr. E. A.), 720
Stalin Prizes for Scientific Studies, 475
Standards Institution, British, Codes of practice for Building and Civil Engineering Work, 578
Staphylococcus aureus, Effect of Certain Chemotherapeutic Agents on Experimental Eye Lesions produced by (Robson, Dr. J. M., and Scott, Major G. I.), 581
Starling Movements and the Spread of Foot-and-Mouth Disease (Bullough, Dr. W. S.), 683
Stars, Profiles of Hydrogen Lines in Two Class B (Douglas, A. Vibert, and West, D. C.), 671; Leander McCormick Proper Motions of Faint (Ali, A.), 142; Magnitudes and Colours of Northern, 53; Nature of the Long-period Variable (Scott, R. M.), 47; New Spectrographic Observations of Peculiar (Struve, O., and Swings, P.), 80; Spectra of Long-period Variable (Merrill, Paul W.), *review*, 155
Statistical Control of Production (Darwin, Dr. C. G.), 573
Statistical Dictionary of Terms and Symbols (Kurtz, Dr. Albert K., and Edgerton, Dr. Harold A.), *review* by M. G. Kendall, 371
Statistical Methods for Research Workers (Fisher, Prof. R. A.), eighth edition, *review* by M. G. Kendall, 451
Statistical Procedures and their Mathematical Bases (Peters, Dr. Charles C., and van Voorhis, Prof. Walter R.), *review*, 151

Statistical Theory of Accident Proneness (Chambers, E. G., and Yule, G. Udny), 466
Statistics, Mathematical Requirements for, *review*, 151
Statistics in Research, Utilization of, *review* by M. G. Kendall, 451
Statistics (Mathematical), Committee Decisions and (Nicol, Dr. Hugh), 473
Statistics (Social Science), and Population Problems (Jones, D. Caradog), 98
Statistics (Vital) of Switzerland, 136
Steel Structures (Simple), Practical Design of (Stewart, Dr. David S.), second edition, Vol. 1: Shop Practice, Riveted Connections and Beams, etc., *review*, 563; Vol. 2: Girders, Columns, Trusses, Bridges, etc., *review*, 205
Steel-maker's Autobiography, *review* by Dr. C. H. Desch, 397
Steels (Modern), Analysis of, *review*, 485
Steric Hindrance, Calculation of (Evans, A. G., and Polanyi, Prof. M.), 608, 665
Stoat *Mustela erminea* L., Change of Pelage in the (Rothschild, Hon. Miriam), 78
Stone-Age Industry from the Wedza District (Radcliffe-Robinson, K.), 225
Stone-Age Man (Modern) in South Australia, 641
Stone Tools (Simple), An Unrecorded Method of Manufacturing Wooden Implements by (Mountford, C. P.), 641
Storms (Magnetic), Cosmic Rays and (Duperier, Dr. A.), 579
Storms (Winter), Use of Snowflake Replicas for Studying (Schaefer, Vincent J.), 81
Street Lighting, Past, Present and Future (Wilson, G. H.), 577
Strength of Metals, A Theory of the (Bragg, Sir Lawrence), 511
Streptolysin *O* (Herbert, —., and Todd, —.), 275
String (Knotted), Autobiography of a Steel-maker (Brearley, Harry), *review* by Dr. C. H. Desch, 397
Structures, Effect of High Explosives on (Bernal, Prof. J. D.), 673; Materials and (Clark, D. A. R.), *review*, 563
Structures (Simple Steel), Practical Design of (Stewart, Dr. David S.), second edition, Vol. 1: Shop Practice, Riveted Connections and Beams, etc., *review*, 563; Vol. 2: Girders, Columns, Trusses, Bridges, etc., *review*, 205
Study (Scientific) of Society (Mess, Dr. Henry A.), 624
Submarine Contours of the North Pacific (Betz, F., and Hess, H.), 359
Submarine Valleys, Glaciation and (Daly, Prof. Reginald A.), 156
Sulphanilamide and *p*-Aminobenzoic Acid, Relative Acidity and Basicity of (Albert, Dr. Adrien, and Goldacre, Dr. Reginald), 245
Sulphonamide Inhibition of Yeast Growth by *p*-Aminobenzoic Acid, Neutralization of (Landy, Dr. Maurice, and Dicken, Dorothy M.), 244
Sulphur Atom, Hydrogen Bonds Involving the (Heafield, T. G., Hopkins, G., and Hunter, Dr. L.), 218
Summer School in Human Biology, 192
Sun, Mechanism of the (Sellers, F. J.), 136; and the Ionosphere (Chapman, Prof. Sydney), 277, *erratum*, 354
Sunspot (Great) of September 1941 (Newton, H. W.), 223
Sunspots and Quasi-eruptive Flocculi, Surges near (Ellison, M. A.), 642
Surge Phenomena, Seven Years' Research for the Central Electricity Board (1933–1940), *review* by Dr. T. E. Allibone, 621
Surgeons, Royal College of, Scientific Report for 1940–41, 107
Surges near Sunspots and Quasi-eruptive Flocculi (Ellison, M. A.), 642
Surges (Electrical), Research on, *review* by Dr. T. E. Allibone, 621
Surnames and Blood Groups, with a Note on a Probable Remarkable Difference between North and South Wales (Roberts, J. A. Fraser), 138
Sweden, Medical Services in (Trietz, Torsten), 468; Population of, 382; Scientific Research in, 407
Swedish Botanical Garden, one hundred and fiftieth anniversary, 191
Sweet Corn (Seakale, Artichoke), Asparagus and Rhubarb, Uncommon Diseases of (Green, D. E.), 641
Switchgear (Transformers and), Mineral Oil for (Pollitt, A. A.), 703
Switzerland, Earthquakes registered from October 1, 1941–January 31, 1942, 636; Vital Statistics of, 136
Symbols (Terms and), Statistical Dictionary of (Kurtz, Dr. Albert K., and Edgerton, Dr. Harold A.), *review* by M. G. Kendall, 371
Symons Memorial Lecture of the Royal Meteorological Society, to be delivered by Dr. H. Spencer Jones, 217
Synthesis (Enzymatic) of Levan (Aschner, M., Avineri-Shapiro, S., and Hestrin, Dr. S.), 527
Synthesis (Microbial) and Autolysis in the Digestive Tract of Herbivora (Baker, Frank), 582
Synthesis, A New X-Ray (Yü, S. H., and Ho, C. P.), 729; A New, of X-Ray Data for Crystal Analysis (Yü, S. H.), 638

TABLES (Formulæ and) for the Botanical Laboratory, *review*, 150
Tanganyika, Health of, 107
Tata (Lady) Memorial Trust, grants or scholarships for 1942, 299; awards for research in blood diseases, 729
Teachers in Technical Institutions (Association of), presidential address on the Future of Technical Education (Cull, H. J.), 615
Teaching of Physics, (*a*) Fundamental Laws and Definitions (Hansel, C. W.), 460; (*b*) The Need for a Permanent Standardization and Guidance Committee for Elementary Physics (Woodland, P.), 460
Teaching of Science, The, 161
Technical Developments in Broadcasting (Bishop, H.), 269
Technical Education (Orba, Alexander), 617
Technique (X-Ray) in the Industrial Laboratory (Rooksby, H. P.), 597
Technology (Science and) in the Soviet Union (Marx Memorial Library and Workers' School Symposium on), 327, 545
Technology and Society, the Influence of Machines in the United States (Rosen, S. McKee, and Rosen, Laura), *review* by D. Caradog Jones, 63
Telecommunication (Radio), Post-War Planning in (Institution of Electrical Engineers (Wireless Section) discussion on), 614
Telegraph Poles, Lodgewood (Amadon, C. H.), 467
Telephony (Long-distance), Voice-frequency Signalling and Dialling in (Radley, W. G., and Wright, E. P. G.), 242
Television in Colour and Stereoscopic Relief (Baird, J. L.), 18
Temperature (Brittle) of Rubber (Selker, M. L.), 645
Temperature and Sex Ratio in *Drosophila pseudo-obscura* (Darlington, C. D., and Dobzhansky, Th.), 670
Temperatures (Low), Concrete at (Yates, J. C.), 360; Oxidation of Hydrocarbons at (George, P., Rideal, Prof. E. K., and Robertson, A.), 601; Properties of Rubber at, 645

NATURE PRESERVATION AND NATIONAL LIFE

THIS War, like the War of 1914–18, with its demand for sacrifice from all the people, has given a jolt to the easy-going tolerance which, in times of peace, permitted the development and the continuance of social conditions universally regarded as intolerable. In Great Britain, at any rate after the War, a reawakening of the nation to its needs, with insistent urge for their satisfaction, are foregone conclusions, and promise of some readjustment of conditions is implicit in the post-war reconstruction policy of His Majesty's Government.

But if post-war reconstruction is not to miss a great opportunity it must not limit its efforts to re-arrangements of industry and populations as between town and country, restoration of security to the basic food-raising industries of husbandry and fishing, banishment of slums and reduction of disease, and similar essays to improve the material welfare of the nation or of its constituents. For the welfare of man's spirit, as well as his material good, demands forethought and planning, and the "nation of shopkeepers" is certain, and properly so, to put the latter first, and perhaps forget the other altogether in the difficulty of attaining throughout the nation even the lowest decent standard of economic independence and health, to say nothing of happiness.

Indeed we can say that one aspect of this more subtle welfare has been forgotten, or almost forgotten, by the Governments which have represented our people—the opportunity for sharing in that pleasure, mental uplift and healthy recreation which is associated with great open spaces and the beauty of Nature. It is a matter in which the Governments of most civilized countries have far out-distanced the leaders of our own nation. Rightly our legislators may plead that the people has never with one voice demanded such amenities, and this cannot be gainsaid, but the position is no different in other lands, for even of the United States, with its enormous area of Nature reserves, it has just been written, "a great part of the public is indifferent to the success of wildlife conservation"*. There the Government, itself guided by a few enlightened pioneers, gave the lead, and now it expends much thought and money in endeavouring to educate the people to make the best use of their own Nature possessions, although of course there is a nucleus of the American nation which takes full advantage of its opportunities.

We plead, therefore, for the inclusion in His Majesty's Government's review of post-war planning, of consideration of the value and the possibility of setting aside as national heritages areas for the people. The difficulties do not appear to be greater than those which have been surmounted in less wealthy nations. Density of population and the area under cultivation offer no greater obstacles here than in many European countries. Indeed, of land which may be regarded as almost unproductive the U.S.S.R. and Spain have about 20 per cent, France 14 per cent, Italy 13 per cent and Germany 9 per cent, while the proportion in Great Britain is roughly 18 per cent. Surely there is room here for the areas we have in mind.

---

* Ira N. Gabrielson, "Wild-Life Conservation", 1941, p. 241.

These areas should be of three kinds, conveniently specified in a memorandum just issued as the result of a conference of representatives of British organizations interested in the provision of national parks and the preservation of the native plants and animals of Great Britain*.

(1) *National parks and national reserves*, of considerable size, open to and providing facilities for the recreation and enjoyment of the public with no more restriction than is necessary to preserve the amenities of the area. Their objects are various, but in general their purpose is to ensure to the people access to areas of wide appeal and to preserve these unspoiled for future generations. Such are typical mountain regions, moorlands and downs, stretches of sea-coast, fen-land, which have some peculiar interest because of their scenic beauty, their geological structure, their association with human history, their plant and animal life, and above all, their suitability for recreation and rest.

(2) Intermediate areas, which we may call *national wards*, "notable alike for their natural beauty and for their scientific interest and often including agricultural areas of great charm, in which all that is requisite for the preservation of their amenities is that they should not undergo any fundamental change". Such areas, and presumably only exceptional areas would be selected, would have to be delimited and preserved from unsightly or injurious industrial development, the operations of the speculative builder and the advertiser. Land in such areas need not be purchased from its owners; the essential is simply that present usage should be continued or should not be replaced by usages less in keeping with the peculiar charm of the place.

(3) *Nature reserves and sanctuaries*. These are areas to be set aside for a very special purpose, the preservation of representative samples of our native wild plants and animals, and of geological features of particular significance. They would include typical marsh and fen such as the Broads, beaches such as Blakeney, woodland such as the ancient pine forest of the Spey Valley, mountain and sea-cliff. Naturally, their special purpose would restrict their appeal to a limited section of the people, and the safety of the plants and animals would demand the least possible disturbance even by naturalists and the Nature-loving public; but the experience of the past, with its tale of the extermination and disappearance of native species, calls for the determined protection of wild life.

Of these three types of area the grandest in dimensions and in purpose is the national park, with its offer to the people of temporary release from the rush and strain of the daily round and of recreation of mind and body by contact with the peace and beauty of unspoiled Nature; and if national parks are to fulfil this object they must be made reasonably accessible to centres of population, and must have within easy reach, if not within their bounds, rest-houses where accommodation is comfortable and food inexpensive. The success of this part of the scheme will rest largely upon careful selection and subsequent planning. But even more will the success of the Nature reserves depend upon the proper selection of areas, for just as their purpose is specific, their locality must be defined by fine adjustment of environment to the needs of the wild inhabitants, plants or animals.

While the selection of the national parks and national wards, therefore, should be in the hands of a composite body including representatives of the Government Departments concerned, of bodies whose interests are in art and amenity, in touring and camping, and in wild life in its broader aspects, the choice of Nature reserves could be most fittingly made by scientific workers, especially biologists, familiar with detailed distribution and the conditions which influence particular species or assemblages of species.

The recent conference, the place and date of the meeting of which, curiously enough, are not mentioned in the Memorandum, made certain recommendations regarding the management of the areas. It suggested that the national parks and national reserves should be administered and managed locally "so far as may be desirable", a qualification which seems to leave the recommendation very much in the air. On the other hand, as regards the specialized Nature reserves and sanctuaries, the management "should be placed only in the hands of persons fully conversant with the highly technical problems included in the maintenance of the balance of life, and the general control should be vested in a central authority representative of the different interests concerned". Since no one has yet fathomed the intricacies of the reactions which make up the balance of life in any area, it may be difficult to constitute the "fully conversant" management committee. Indeed the great value to scientific knowledge of these ecological oases will be the opportunity they afford of continuous study under known conditions of the interplay of weather, soil, vegetation and fauna. How much that is required is indicated by the confession of the director of wild-life conservation in the United States: "the research undertaken in this country [U.S.A.] has never yet been great enough to meet the needs of conservation in any of its phases" (*op. cit.*, p. 243).

---

* Nature Preservation in Post-War Reconstruction. Conference Memorandum No. 1. Issued on behalf of the Conference of the Society for the Promotion of Nature Reserves. November 1941.

So far as wild life is concerned, there are three broad principles which must guide the national park authorities to be created to determine general policy, if the report of the National Park Committee (1931) is followed. They are clearly set out by the Director of Fish and Wild-life Service in the United States Department of the Interior (*op. cit.*, p. vi). The first is that wild-life conservation is not an isolated problem but is inseparably linked with problems of soil, water and forest, and that all must be regarded together in a comprehensive policy. The second is that wild life must have an environment, animate as well as inanimate, suited to its needs if it is to survive. The third is that any use that may be made of any wild creature must be limited to the destruction of not more than the annual increase if the breeding stock is to be kept up, with the correlative that those animals and plants which are inordinately successful in the competition of life and tend to oust less robust neighbours must be kept ruthlessly within bounds. The successful sanctuary is not necessarily a place where *all* animals and plants are protected, for indiscriminate protection may well lead to the survival of the only species of plants or animals which need no protection, and to the consequent disappearance of the very forms for which a sanctuary was necessary.

It is unlikely that even the national parks, the areas of which are bound to be limited, will satisfy the craving for variety of scene and for the stimulus of unexpected prospects which is the inheritance of most men and particularly of such as the artist and the Nature wanderer. So that, with the formal reservations which have been mentioned, it behoves an enlightened Government to take further steps to preserve, and encourage appreciation of, the grander aspects of our varied scenery. A danger lies in the clash between business and Nature—the spread of industry to an unspoiled valley with perhaps the consequent pollution of miles of river and other deteriorations, the construction of ponded valleys in the Highlands as a source of electric power, entailing changes in the water supply of a watershed, the felling of great stretches of forest without compensatory planting. While no negative policy should be allowed to stand in the way of efforts which are to benefit vast multitudes of people, nevertheless a wise control would see to it that the benefits mentioned here were gained without serious disturbance to scenery.

It is sometimes forgotten that the great steps in the progress of civilization transformed the aboriginal landscape: the development of agriculture drained the marshes, destroyed the lowland forests, and replaced variety of vegetation by uniformity, just as the domestication of animals contributed further to the disappearance of woodland for the sake of pasture, and intensified the changes in plant life. What we now look upon as natural landscape is not the landscape of our forefathers, and it may be that the increasing comforts of civilization can only be gained by some sacrifice of aboriginal Nature. There is the more reason that further encroachments should be guided and localized, and that certain selected areas should now be set aside and should be preserved for all time as representative of the scenery and of the haunts of the wild life of the British Isles.

THE SCIENCE OF MERCERIZING

Mercerising

By J. T. Marsh. Pp. xv+458+56 plates. (London: Chapman and Hall, Ltd., 1941.) 32*s*. net.

WHEN cotton hairs are treated with a concentrated solution of sodium hydroxide in the cold, they combine with alkali and undergo a remarkable series of changes. The cellulose swells in such a way that the flattened cross-section becomes elliptical, with fairly complete disappearance of the lumen, and lateral swelling is accompanied by a decrease in length. Such phenomena, and the increased affinity for dyes of the alkali-treated hairs, as well as their increased strength, were first observed by a Lancashire chemist, John Mercer, in 1844–1850. After an interval of some thirty years, Mercer's observations were turned to practical advantage in the manufacture of crêpes, but the mercerizing process proper did not come into being until 1890, when a twenty-year-old chemist, Horace Lowe, discovered that cotton acquires a greatly increased lustre when the hairs are tensioned so as to prevent shrinkage during the caustic soda treatment.

As one of the most important processes in the cotton textile industry, mercerizing has occupied the attention of numerous research workers, especially during the past twenty years, and published work on the subject now exceeds in volume that on any other aspect of cellulose chemistry. Systematic studies of the changes in form undergone by cotton and related fibres in solutions of the caustic alkalis have been undertaken ; the mechanism of swelling has been elucidated, largely as a result of Neale's investigations ; changes in fine structure have been examined by X-ray methods ; and the properties of the mercerized product have been defined.

These achievements are, to a large extent, due to the awakening of the industrialist during the War of 1914–18 to the advantages which would accrue from the application of the scientific method even to such well-established processes as those of the textile industry. From the resulting activities of the private research laboratories, research associations and research workers in the universities, textile technology has been advanced from a state of simple empiricism to that of an exact science. The pace of recent advances in knowledge has been such that the man of science, having much to learn from the craftsman, has had little opportunity of collating his new-found knowledge in the form of text-books suitable for use by the student. Even now, most of the books in common use belong to the empirical age in textiles, and are unworthy of the new dignity of the subject. No such criticism, however, can be applied to Mr. J. T. Marsh's recent work on mercerizing. Out of his long experience as a research worker in the field of cellulose chemistry, he has compiled a survey of the literature of mercerizing which is both authoritative and interesting.

Commencing with a vivid account of the work of Mercer and Lowe, Marsh proceeds to discuss the growth and structure of cotton hairs and their dimensional changes in caustic soda solution, as a preliminary to a comprehensive account of mercerizing practice. This half of the book contains many illustrations of the beauty of the scientific method in textile technology, such as the proof that the swelling of cotton hairs in aqueous solutions of alkaline hydroxides depends on the degree of hydration of the alkali ion, and Adderley and Oxley's discovery that tables of doubling twists may be replaced by the simple rule that maximum lustre is obtained when the doubling twist is seven tenths of the original twist in the component yarns. The second half of the book is concerned mainly with the theoretical aspects of the action of caustic alkalis on cellulose. Neale's work on the swelling of cellulose, and Urquhart and Williams' studies of the moisture relations of mercerized cotton, receive exhaustive treatment in chapters which are among the most interesting in the volume. The methods which may be employed to assess the efficiency of the mercerizing process, and to identify causes of faults in the finished product, are discussed in the concluding pages.

In the main, the author has adopted the historical method in developing the different sections of his book ; no important paper fails to receive discussion, but undue space seems to be given to the now discarded work of early investigators. In addition, the reader is left with the impression that the author has had some difficulty in deciding the order in which the different sections of his subject should be treated. There are re-entrant points in the argument, and a more logical development might have been first to discuss the theoretical aspects of the action of caustic alkalis on cellulose, then the dimensional changes undergone by cotton hairs, followed by mercerizing practice and the evaluation of the finished product. Despite these defects, the book forms a most welcome addition to the literature of textile technology. It is particularly well illustrated, and besides being helpful to the research worker, should play an important part in the training of the future industrialist.

J. B. SPEAKMAN.

FUTURE OIL PROVINCES OF NORTH AMERICA

Possible Future Oil Provinces of the United States and Canada

A Symposium conducted by the Research Committee of the American Association of Petroleum Geologists, A. I. Levorsen, Chairman. Papers read at the Twenty-sixth Annual Meeting of the Association, at Houston, Texas, April 1, 1941, and published in the Association Bulletin, August 1941. Edited by A. I. Levorsen. Pp. vi+154. (Tulsa, Okla. : American Association of Petroleum Geologists, 1941.) 1.50 dollars.

THE authors of this symposium, in their review of possible additional sources of oil in Canada and the United States, are not concerned with the discovery of single fields or leases, nor yet with extensions of existing fields. Rather are they grappling with the problem of discovery of reserves in areas as yet only partly explored and in which there is every prospect of finding, not one pool, but many pools, sufficiently large to be of significance in assessment of the nation's total reserves.

The views expressed are for the most part not those of individuals, but represent the collective findings of committees appointed by various geological organizations to compile this inventory. There are, for example, contributions from the Rocky Mountain Association of Petroleum Geologists and the Pacific Section of the American

Association of Petroleum Geologists; also from the Geological Societies of Tulsa, West Texas, etc. Each of the nine articles contained in the symposium includes a description of provinces, in the region for which the authors are responsible, which have been selected as favourable from the point of view of future oil resources. Considered reasons are given for their selection, and beliefs substantiated by sketch maps and sections showing the general geography, structure and stratigraphy of potentially productive provinces. Moreover, to stimulate cohesion and enable the reader to frame an opinion of total reserves of this character throughout the United States and Canada, unexplored territory is critically reviewed from the point of view of four criteria considered, if present, as being favourable to oil accumulation. These are: areas of sedimentation, preferably marine, variable and unmetamorphosed; seepages; unconformities; and the known presence of wedge belts of porosity.

A map depicting regions of possible future oil provinces as described in the symposium indicates that approximately two fifths of the total area of the North American continent falls into the category of potentially favourable territory. It is refreshing to visualize the magnitude of unexplored reserves in this way rather than to be faced, as one so often is, with quantitative estimates of potential reserves running into billions of barrels and having little claim to accuracy. Surely the bugbear of the industry, fear of exhaustion of resources, will loom less large when it is realized that there are such vast areas of untried territory. Calculations of reserves cannot properly be made until geologists have completed the almost limitless task of exploring such mighty terrains as are described in this symposium. Even then, no claim could be laid to have exhausted possibilities of new resources in these two countries.

CANADIAN ARCTIC BOTANY

Botany of the Canadian Eastern Arctic

Part I: Pteridophyta and Spermatophyta. By Nicholas Polunin. (National Museum of Canada, Bulletin No. 92.) Pp. vi+408. (Ottawa: King's Printer, 1940.) 1 dollar.

WORK on the flora of the Canadian Eastern Arctic has been dogged by misfortune. James M. Macoun, chief botanist of what is now the National Herbarium of Canada, made several expeditions into the western part of the area, collecting a wealth of material, but died before his father in 1910. His prospective collaborator, Theo. Holm, had in 1902 promised at an early date a work on the Hudson Bay flora, but died before he completed it. Thorild Wolff died in 1917 crossing the extreme north of Greenland before he reached the area he chiefly set out to explore. M. O. Malte, successor to Macoun as chief botanist at the National Museum, in 1927 began work in earnest in collaboration with C. H. Ostenfeld, director of the Botanical Garden, Copenhagen, a well-known specialist in the Arctic flora. Ostenfeld died in 1931 and Malte in 1933, but during these few years Malte made three voyages in the Canadian Eastern Arctic, collecting more than ten thousand sheets of specimens.

The field therefore lay open ready for Nicholas Polunin, a young botanist with a bent for Arctic travel, who in 1930, when a college student, made a botanical trek across Arctic Norway and Lapland; in 1931 as botanist to the Oxford University Expedition investigated Akpatok I. (Labrador); and in 1933 alone crossed and recrossed Spitsbergen in 2½ days. In 1934, on the Hudson Bay Company's supply ship, he visited all the more important northern ports in the Eastern Canadian Arctic, and in 1936 made a similar voyage with the Eastern Arctic Patrol. From autumn 1935 he had spent more than a year revising all the Arctic material in the Gray Herbarium of Harvard University, and in some Canadian museums. The Canadian authorities, finding so much work already done, offered their support if Polunin would complete, for them to publish, a flora of the Canadian Eastern Arctic, of which, after more than two years' further solid work, the volume before us is the first part. Parts II, "Thallophyta and Bryophyta", and III, "Vegetation and Ecology", are ready for printing, and Part IV, "Subarctic Regions", is well advanced. The Canadian authorities deserve thanks for producing this useful volume in these difficult times, and it is hoped that the remaining parts will appear with as little delay as possible, for the systematic keys for the identification of the flowering plant species—greatly needed by students of the Arctic flora, who at present are forced to acquire the necessary knowledge by laborious and time-consuming delving in an extensive and scattered literature—were relegated to Part IV, as that part would include a much greater number of species, some of which will probably be discovered in the area covered by the present volume.

As it stands, however, this work will be invaluable to students, since it collates all material from the area in fourteen American and European institutions, which together house the greater part of the specimens ever collected there, and in addition provides an extremely full bibliography of the literature, which has been thoroughly digested by the author. The work is not, however, a dull compilation of already published material. Polunin has himself revised all identifications, and in addition contributes to the account of individual species valuable notes resulting from his own field observations and herbarium study. As a result, the book is full of useful and interesting information, not only taxonomic but also ecological and miscellaneous. All doubtful records have been investigated, and when species have been excluded the nature of the error is exposed as fully as possible.

The introduction begins with the geography of the area, which includes "all land in Canada lying north of the 60th parallel of latitude and east of longitude 95 degrees west, with the exception of Axel Heiberg Island, Boothia Peninsula, and the inland parts of Keewatin". For the grouping of individual records, this area is divided into ten districts: Ellesmere; Devon, Cornwallis, and Somerset Islands; Northern Baffin; Central Baffin; Southern Baffin; Melville Peninsula; Northernmost Labrador; Northern Quebec; Islands in Hudson and Ungava Bays; West Coast of Hudson Bay (Keewatin). The boundaries of these districts are shown on a sketch map in the text, but not on the larger map supplied, and unfortunately the authorities did not see their way to arrange for the insertion on the latter of the numerous localities mentioned by collectors on labels, although the inclusion of these would have greatly increased its value. The difficulty of tracing place-names so used without any indication of their whereabouts—such as 'Shift-rudder Bay', 'Floeberg Beach'; 'Dumbbell Harbour', and the like—is here solved by the inclusion (pp. 3–11) of the latitude and longitude of almost all such localities. The necessity of this is shown by the fact that even when such essential names as Baffin Island are counted, less than two-fifths of the names in these lists are shown on the map, and it is to be hoped that the authorities will reconsider their decision and issue a more satisfactory map with a subsequent part.

The second part of the introduction gives a brief summary of the "History of Exploration" in the area, and includes an alphabetical list of collectors with dates and localities, extremely useful to workers in herbaria. An undeserved slur is cast on Robert Brown, of whom it is said that he, "in compiling a botanical appendix to Ross's report (1819), 'lumped' the Greenland plants with those of our area, so that with a few exceptions I am unable to cite them." Robert Brown was a most meticulous worker, and the 'lumping' was due to the fact that for the most part the specimens—now in the British Museum—apparently never had any indication of the place where they were collected. It may even be that Robert Brown made such strong comments on this that the specimens collected on Parry's voyages a few years later were precisely localized, for in those days it was commonly considered that a very general indication of locality was sufficient.

Except for the acknowledgments of help, the remainder of the introduction deals with the plan, scope, and methods of the catalogue itself. The author estimates that he has examined and determined between fifty thousand and sixty thousand records. He writes: "It will be noted that my conception of species is rather broad—that I tend to be a 'lumper' rather than a 'splitter'. My varieties are the subspecies of some authors, and even the microspecies of others—entities which in possessing several 'characters' of distinction from the rest of the species, and in having a geographical distribution of their own, are 'on the way to becoming species'." (It may be remarked that these features, namely, correlation of distinct characters and a distinct distribution, are precisely those which I have frequently insisted on as being the twin essentials of specific difference, and these groups are better termed subspecies.) "My *formæ* are entities which, in our own state of ignorance concerning the genetics and cytology of most groups, are assumed to be of lesser taxonomic significance. They are often striking enough in their differences from the typical . . . form, at least in the apparently less conservative characters, but still are presumably mere phases, which lack on the one hand a real *group* of hereditable characters, and on the other a geographical range distinct from the rest of the species." (The term *variety* would be more appropriately applied to such still unresolved *variations*.)

All critical groups have been investigated by the author himself, a course possible in dealing with the reduced flora of the Arctic regions. Although the order and nomenclature are in general those adopted in the Gray Herbarium, Polunin has preferred to investigate these matters for himself, rather than to adopt them without question. The care with which both kinds of investigation have been conducted is shown throughout the volume by the usefulness of the notes which embody these researches.

The catalogue itself comprises 297 species, of which four are new, and a total of 399 named forms, including ten new varieties and nine new forms; most of the novelties are illustrated. Of all these, not one appears to have been introduced by the agency of man, although the area dealt with is some 420,000 square miles of land. Man is, however, a rarity in these regions. Of the 297 species, nearly two hundred occur also in the European Arctic, and between eighty and ninety in Britain. The severity of the climate of this part of boreal

America is indicated by the fact that in Europe north of the 60th parallel more than a thousand species occur, and even in Greenland about four hundred species are known.

Each species in the catalogue is dealt with in a uniform manner. The name is followed by only such important references and synonyms as are required for identification, the rest of the nomenclature being obtainable through the index. Then follows, in most species, "a discussion of the systematic position, with special reference to the range of variation that it exhibits in or near our area; also, when possible, notes on its morphology, flowering and fruiting, and on any other features of special interest."

These discussions of taxonomy and variation are much more informative than the usual bald citation of names in synonymy, and the readable and vivid style in which they are written is more likely to impress the information on the mind than the stereotyped frigidity which is nowadays so often considered to be required in scientific publications. For example, of *Carex bicolor* All. (recently recorded from the Outer Hebrides), "This most characteristic and attractive little sedge, with its more or less pendulous spikes of rounded, pastel-green fruits peeping out from behind dark scales, although not uncommon in places, appears never before to have been recorded from within our area, or, indeed, from anywhere in the Arctic Archipelago . . . ; also *Lycopodium Selago* L. . . . it is reported by Victorin of this species that 'toutes les tribus sauvages du littoral de l'Alaska mâchent les tiges en avalent le jus pour produire une sorte d'intoxication'; but I can neither find any confirmation of this in the literature or by enquiry from travellers in the region, nor obtain any such effect on myself. Certainly the Eskimo of the Eastern Arctic regions do not use it or any other plant in this manner; indeed, except for the occasional dressing of wounds with *Sphagnum* and the use of various plants both higher and lower for food (generally quite irregularly; they will eat almost anything at times), they do not seem to apply any plants or plant products to their bodies either internally or externally, in marked contrast to their Indian neighbours. . . ."

After these notes the "General Distribution" of the species outside the area is given, followed by the "Eastern Arctic Distribution", or general distribution within the area. Then, under "Occurrence", come "details of the relative abundance of the species in the various parts of its range in our area; also notes on its habitat and ecology, and on its importance as a component of the vegetation. [The ecological notes are mainly based on the author's own observations.] The consideration of each species is concluded by the detailed citation, under the ten major districts headings mentioned . . . of the specimens of it that have been found within our area, or, in the case of the commoner plants, by generalized statements under the same headings."

In the detailed citation of records in critical groups, including as it does indication of the herbaria in which specimens exist and of previous identifications, lies one of the great values of this work. For until the end of last century the existing material was generally scanty and widely scattered, the literature equally so, and consequently identification, especially in critical genera, was frequently very unsatisfactory, wherefore systematists using herbarium material as a basis for their own determinations were often misled and the already existing confusion became worse confounded. Robert Brown, pioneer in the field, working out the results of the first of Parry's voyages, of which his "Chloris Melvilliana" still stands unshaken as the foundation of the literature of the American Arctic, worked with such care that Parry, anxious to obtain quicker determinations to include in his report for the Admiralty, became impatient, and sent the material of his subsequent voyages to W. J. Hooker. Hooker, who was not, as a critical botanist, of the calibre of Brown—*botanicorum facile princeps*—"lumped" together the species of critical genera. From this it followed that, in precisely those genera where the need for well-named material was greatest, herbaria normally contained different plants mixed under the same name, until it was unfortunately too true, as Dr. J. Lid of Oslo once remarked to me, that most Arctic collections were very badly named, and require thorough revision by a specialist in the Arctic flora. This revision has now been admirably made for the Eastern Canadian Arctic. The debris of the past has been cleared up and a good foundation for the future laid down. In an area so extensive a great deal must still remain to be done, but a much-needed work has been accomplished.

One may disagree with the treatment of certain genera or species. My own experience convinces me that the Arctic Cochlearias are not all one species; but every student of this difficult genus seems to produce a different solution of its undoubted intricacy. The "*Zostera marina*", isolated in Hudson Bay in water "probably almost always below 10 C.", is more likely to be the more boreal *Z. Hornemanniana* Tutin. But specialists will be able to criticize any comprehensive work for yet a long time to come, and the present volume certainly calls for compliment on its general soundness rather than criticism in detail. It remains but to add that it is well set out, well printed (with few misprints), and very thoroughly indexed.

A. J. WILMOTT.

Herbs for Daily Use in Home Medicine and Cookery

By Mary Thorne Quelch. Pp. 328. (London: Faber and Faber, Ltd., 1941.) 8*s.* 6*d.* net.

THERE are here numerous pleasant anecdotes of the useful plants of our islands, culled from authorities both ancient and modern. The range is from Dioscorides through the herbalists—Gerard and Culpeper especially—to a gypsy woman "whose herbal lore I shall quote many times". This promise is amply fulfilled. There are recipes for unusual dishes and cosmetics. Among the former "the boiled nettles, as described, may be surrounded by poached eggs". Among the latter, to prepare a cold cream, "if two ounces of glycerine are purchased". Alas, 'tis "if" indeed. The bulk of the book is concerned with medicinal purposes. As it is for the home, safety is wisely put first and the drug plants of the pharmacopœia are dismissed under the entry "poisonous plants". The use of the yellow flowers of celandine as a cure for jaundice is derided as an example of the doctrine of signatures; but, on reading later that beetroot is "of value to anæmic women and girls", you wonder if the superstition is so dead after all. Old wives' simples may be traditionally mated with old wives' tales, but they include (p. 272 under review) raspberry-leaf tea as an aid to easy labour, a prescription which has recently been lifted into official respectability. Here is a good half-hour's browsing to be taken over the nuts and wine.

Butterflies

A Handbook of the Butterflies of the United States, complete for the Region North of the Potomac and Ohio Rivers and East of the Dakotas. By Prof. Ralph W. Macy and Prof. Harold H. Shepard. Pp. vii+247. (Minneapolis: University of Minnesota Press, 1941.) 3.50 dollars.

THIS handbook forms an admirable short guide to all species of butterfly inhabiting the region it is intended to cover. The area in question includes the United States and adjacent Canada lying to the east of Nebraska and the Dakotas and as far south as the northern borders of Missouri, Kentucky and Virginia. The only other book that treats in any detail of the butterflies of the territory referred to is the large, expensive and long out-of-print work of S. H. Scudder.

The chief purpose of the present book is to make identification as easy as possible. Keys to the species of each family are followed by individual descriptions, notes on habits, on distribution, on the larva and its food plants, times of appearance, manner of flight and so forth. The collector will consequently find a good deal of information written in an attractive style and in a brief, concise form. The book should have a ready sale among individuals, secondary schools, and colleges of the United States and parts of Canada. The price is very reasonable considering there are four good-quality coloured plates and a number of photographic text-figures. A. D. I.

British Scientists

By Sir Richard Gregory. (Britain in Pictures Series.) Pp. 48+12 plates. (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1941.) 3*s.* 6*d.*

THIS little book puts in the simplest possible way some of the facts about the life and work of the great British men of science. Though containing only fifty pages, it is illustrated with twelve coloured plates and nineteen other illustrations. It is the sort of book which might be distributed in large numbers to soldiers and other large sections of the population who wish to know something of those who have had, it is increasingly realized, a most profound influence on the destiny of the human race. The book should also be suitable for readers in foreign lands, who are hazy about the existence and achievements of British men of science.

The information in the book will generally be known to scientific workers. They may not, however, have seen before coloured reproductions or the originals of several of the illustrations. For example, the picture of the third Lord Rayleigh working in his shirt sleeves in his laboratory is reproduced in colour. Then there is the painting from the University of Birmingham of Sir Oliver Lodge; the long, red doctor's robe, emphasized by his great height, comes out brilliantly. In black and white, there is Francis Dodd's drawing of Rutherford.

There are some misprints in the list of dates given at the end. These might be corrected in future editions. J. G. CROWTHER.

Physics of the Air

By Dr. W. J. Humphreys. Third edition. Pp. xiv+676. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 42*s.*

THIS book has reached the status of a classic of meteorology; the few weaknesses of the first edition having been for the most part remedied in the second, the third edition needed little more than bringing up to date by the addition of references to the advances of the last ten years. These additions have necessitated the writing of a number of new paragraphs, notably on the effect of clouds on incoming and outgoing radiation, energy equations of evaporation, and zones of silence in meteorological acoustics, the latter remedying a serious omission in the second edition, while throughout the book existing paragraphs have been expanded to take in work published up to 1939. In a few cases the additions are disappointing; for example, the subject of air-mass identification was surely worth more than a half-page, and the "principal Ice-age theories" do not include the well-known solar pluvial theory associated with the name of Sir George Simpson. As a whole, however, the book remains equal to its expressed purpose of providing an orderly assemblage of facts and theories, equally valuable as a text-book for advanced study or a work of reference on a meteorologist's shelves. One unfortunate misprint has crept into the list of contents, where atmospheric refraction has been included under "Reflection phenomena".

The Second Yearbook of Research and Statistical Methodology :

Books and Reviews. Edited by Oscar Krisen Buros. Pp. xxi+383. (Highland Park, N.J.: The Gryphon Press, 1941.) 5 dollars.

THE second issue of this Yearbook maintains the high standard of the first issue, covering the years 1933–38. Being greatly enlarged, it exhibits more fully the advantages of this original method of gathering in a single work of reference the critical and descriptive reviews which have appeared upon the literature in this branch of science. The excerpts presented in this Yearbook are longer and more informative than those in the first volume. The material covered has been extended, especially in mathematical economics, population studies and general histories of science. The appearance of the volume has been improved in many ways, including the use of larger type, and, although a work of this kind was particularly needed in respect of statistical methodology, the value and convenience of this venture should encourage the application of the same principles with respect to other branches of scientific literature.

Within the field with which the reviewer is most familiar, the excerpts from reviews have been made judiciously, and adequately represent the point of view and critical contributions of the reviewers, in addition to giving indirectly a good idea of the works noticed.

Since review notices are particularly liable to be scattered and inaccessible, it is a very great convenience to have them collected, reproduced, and well arranged. R. A. F.

An Introductory Course in College Physics

By Prof. Newton Henry Black. Revised edition. Pp. viii+734. (New York: The Macmillan Company, 1941.) 3.75 dollars.

THIS is a revised edition of the author's "College Physics" first published in 1935. The course is one which would suit most schools, though the author had in mind the needs of definite types of students. In this connexion, there is a slight bias towards physiology and medicine. Also it is pleasing to note that consideration is given to those students studying physics for the sheer joy of it, not with the view of taking any special examination; hence many applications to modern machinery and household devices are included.

Throughout the book emphasis is laid on fundamental laws and principles, and theories are introduced only in so far as they seem helpful in understanding significant facts. There is a good selection of numerical examples graded in difficulty, and the many labelled diagrams are very good; such diagrams are most helpful to students, and they save much descriptive matter.

The book runs to 734 pages, and a lot of ground is covered, but one feels that in some cases more should have been made of certain topics. For example, in view of the great importance of sound in modern applied physics, this section is rather thin; in a book covering the whole field of elementary physics, however, it is obviously impossible to treat all the subjects fully. The book is very well produced, and it is certainly a most useful addition to school physics books.

Intermediate Electricity

By Robert W. Hutchinson. Pp. viii+628. (London: University Tutorial Press, Ltd., 1941.) 12*s.* 6*d.*

THIS book is intended to replace the author's well-established "Text-book of Electricity and Magnetism", and it must be said at once that it is an exceedingly useful book.

The treatment is on modern lines, and a pleasing innovation is an introductory chapter on the modern theory of electricity and electrical phenomena; here the facts are stated simply, and they form a useful background for the student's future work. Another pleasing feature is the stress laid on the fact that magnetism itself is merely a phase of electricity, and it is refreshing, though unusual, to find the topics of terrestrial magnetism and atmospheric electricity discussed in the same chapter.

There are numerous fully worked examples; this is a good feature, especially for those students working alone. Emphasis is also rightly laid on the importance of units; neglect of this work often leads to confusion when students tackle numerical problems. The author does not set out to cater for any particular examination, but the book more than covers the needs of those students preparing for the Intermediate Science, Higher School Certificate and Scholarship examinations. The mathematics in the book should be well within the compass of these students, though the average student may find the mathematics in the chapter on alternating current and varying currents rather formidable.

In spite of its rather high price, the book is excellent value, and if a student can afford it he will find it extremely helpful and useful.

Handbook of Economic Entomology for South India

By Dr. T. V. Ramakrishna Ayyar. Pp. xix+528. (Madras: Government Press, 1940.) 4.12 rupees.

KNOWLEDGE of South Indian insects has greatly increased since the publication of T. B. Fletcher's book on the subject in 1914. This work is now out of print and there is a growing demand for its replacement by a more modern book. As a desideratum it has been filled by the appearance of Ramakrishna Ayyar's volume that is now before us. This writer is very well qualified for the task, having many papers and bulletins on South Indian economic entomology to his credit. The book is divided into two parts, and Part I deals with general aspects of the subject such as anatomy development and classification. Part II is in the main a conspectus of the chief injurious insects of South India and the best-known methods for combating them. The book is well printed and seems to be very free from errors, while its numerous illustrations add materially to its value. It should meet with a wide and speedy acceptance and fill a definite place in the literature of Indian economic entomology.

ANGLO-AMERICAN CO-OPERATION IN SCIENTIFIC RESEARCH

By PRESIDENT JAMES B. CONANT, For. Mem. R.S.

THE following address by President James B. Conant, of Harvard University, was arranged to be given on September 26 before the Conference on Science and World Order, under the auspices of the British Association for the Advancement of Science, in London. The address was made on a record in Washington and flown across the Atlantic for rebroadcast to the Conference. Unfortunately, it failed to arrive, but the following copy has recently reached us.

I assume that through the United States Ambassador, Mr. Winant, you have asked me to address you because of the fact that I am chairman of the National Defense Research Committee, an arm of the United States Government. In that capacity, it is perhaps fitting that I should have something to say about the mobilization of science in the United States and the co-operation of British and American men of science for the war effort. On the other hand, many things that I have said as a private citizen of the United States concerning the foreign policy of my country would be entirely inappropriate in this address. To some of you my views are known. I can only say that I hold them with greater conviction every day. Many of my fellow men of science and academic colleagues on this side of the water are of the same opinion—others have disagreed. That a great debate has raged in the United States about the extent and nature of our participation in the war against Hitler will be no surprise to a British audience. For if I read your recent history rightly, it was not a matter of weeks or even months, but rather of years before the citizens of your country were able to resolve the deep conflict between the ideal of peace and the ideal of freedom, between their hatred of war and their hatred of the Nazi philosophy of tyranny and fear. For I take it these were the elements which determined the development of your own foreign policy before the War.

But in one matter I can brush aside all harassing ambiguities. On one point all American men of science are agreed. They unite in saluting the bravery of the British nation; they applaud unanimously your gallant stand. Moreover, as scientific workers they are proud of the vital parts their fellow-workers of Great Britain are playing in the struggle now in progress. They realize, though often only dimly, that history will surely record this heroic struggle as a defence against overwhelming odds not only of Great Britain but also of individual liberty throughout the world.

In June 1940 the first realization of a world crisis aroused the United States. Amidst violent debates on foreign policy, a vast programme of rapid rearmament was initiated. As to the necessity of producing at top speed a great quantity of instruments of war there could be but one opinion. In these circumstances it was essential to mobilize the scientific talent of our country with all haste. The National Defense Research Committee, with Dr. Vannevar Bush as chairman, was then created by Presidential order. Its task was not advisory, for the scientific advisory bodies of the Government had long been in existence. The National Academy of Science, a parallel of your Royal Society, has by Congressional charter the duty of advising the Federal Government on scientific matters. The National Research Council, a creation of the Academy, has functioned effectively to that end for many years and still continues to play an active part, particularly in the field of medical research. What was needed was not another advisory body but an executive agency capable of bringing available scientific talent as soon as possible in touch with the army and navy; an executive agency to speed up the scientific research on instrumentalities of war by drawing on the existing laboratory facilities of the whole country. This was the function the National Defense Research Committee was created to fulfil.

The new Committee was composed of six civilians together with a representative of the Secretary of War and a representative of the Secretary of the Navy. Rather than establish any large organization of its own, the National Defense Research Committee decided to use its available appropriations through contracts with universities and industrial firms which would carry on specific research and development on secret matters pertaining to modern warfare. Through various sub-committees or divisions, each headed by a Committee member, the work was soon divided. To my lot fell chemistry, to Prof. K. T. Compton, of Massachusetts Institute of Technology, fell one branch of physics, to Jewett and Tolman were assigned still others. Liaison officers from the Army and the Navy were attached to the various sub-committees. In this way the men of science brought into the new work were kept in active touch with members of the Armed Forces.

During the past year, more than ten million dollars have been spent through 270 contracts placed with 47 different universities and technical colleges and 153 contracts placed with thirty-nine industrial firms. Needless to say, great precautions have been necessary to insure the secrecy of the work. No man has been brought into the organization either as a member of a sub-committee or as a contractor without the approval of the Army and the Navy. Great care has also been taken to ensure secrecy in the placing of the contracts either with academic workers or industrial firms.

In both physics and chemistry the effort has been to distribute so far as possible the problems to different investigators throughout the country. In this way, during the initial year at least, the normal functions of our universities were, so far as possible, undisturbed. In a few cases the nature of the work has made such an arrangement quite impossible. In one case in particular, the Radiation Laboratory at the Massachusetts Institute of Technology, it was essential that a large group of physicists should be assembled to work on a highly confidential and important subject with the greatest possible speed. Therefore, more than 150 different physicists from twenty-five different universities in all parts of the country have been brought together to work towards a common goal. We estimate that approximately a thousand scientific workers, ranging all the way from senior professors to young research workers, are now at work in one way or another in academic institutions under contracts with the National Defense Research Committee. In addition, more than seven hundred scientific workers of the same grades are at work in industrial firms in connexion with the contracts which have there been placed. As in your own country, we have found that the nature of the problems in this War are such that physicists and certain types of engineers are in greater demand than chemists. Indeed, it would appear from a survey that has recently been made that probably 75 per cent of the more distinguished research physicists of the country (those starred in the "American Men of Science") who are available are now at work on war problems. I hazard the opinion that it will be only a few months before the remaining 25 per cent are equally involved.

The success of the undertaking has been due in no small measure to the effectiveness of Dr. Vannevar Bush, both as a man of science and as an administrator. Dr. Bush was the chairman of the Committee during the first year of its existence and shouldered the responsibilities for the enormous task. Three months ago, by order of the President, he was made director of a newly created Office of Scientific Research and Development. In this capacity Dr. Bush was charged not only with many of the responsibilities which he had formerly carried as chairman of the National Defense Research Committee, but with the further task of co-ordinating scientific research on medical problems affecting national defence. Most important of all, he has the charge of co-ordinating, and where desirable, supplementing the scientific research activities carried on by the Departments of War and Navy and other agencies of the Federal Government. The National Defense Research Committee now becomes a part of the new Office of Scientific Research and Development, and I, as the new chairman, am responsible to Dr. Bush.

Parallel to our Committee is a newly formed one on medical research, of which Prof. Alfred N. Richards is chairman. Together these two Committees will be the main instruments which the Office of Scientific Research and Development will use to carry out the task entrusted to it by order of the President of the United States.

Such, in brief, is the organization which has been created to bring about the rapid mobilization of scientific talent in the United States to aid the Armed Forces of the Federal Government. Those who are interested in problems of organization and administration will note that the scheme is both flexible and temporary. It is clearly designed to last only during the period of national emergency. No new permanent organizations are created, no new Government laboratories are built or staffed, no large administrative offices are established. Rather a method was devised by which with all speed possible the available scientific talent and available laboratories of the country could be used to supplement the already existing research establishments of the Army and the Navy.

One of the happiest results of the past year's labours has been the ever-increasing Anglo-American co-operation in scientific fields. This was at first made possible on our side of the water by the National Defense Research Committee; it is now a function of the new Office of Scientific Research and Development. The Executive Order which established this office with Dr. Bush at its head provided that the Director should initiate and support such scientific research as may be requested by the Government of any country the defence of which the President deems vital to the defence of the United States under the terms of the Lease-Lend Act of March 11, 1941. As many of you know, we have had in London since last March American scientific liaison officers, Mr. Hovde and Mr. Lewis. It was my privilege to come to England with Mr. Hovde and to initiate the exchange of research information on instrumentalities of war. From the first moment of our arrival, we met a cordiality and openness of welcome that made evident your whole-hearted interest in co-operation. I trust the British representatives in Washington have formed a similar opinion of the American attitude.

After more than six months of work our interchanges of information and of workers have yielded results of considerable importance. I believe that we on our side of the Atlantic have contributed something to your great effort, and I hope and pray that our contribution before many months are past will be of the first order of importance; for I know I am speaking for my fellow-workers in the National Defense Research Committee when I say that nothing would give us more satisfaction than to feel that through our work we had contributed directly to the effectiveness of the war effort. Our eagerness to help can scarcely be over-estimated; may the future demonstrate that our capacities have been equal to our desires!

I cannot conclude without referring briefly to what must be to some extent in everyone's mind at this Conference—the world we are going to live in after the War is over. It is not for me to outline a world order or even to express views on Anglo-American policy. But no intelligent man who on one hand loves peace, and on the other places the highest value on individual liberty, can doubt that without some form of co-operation between our two countries no peace worth fighting for can be established. Similarly, no intelligent man who consults his head as well as his heart can fail to note great obstacles that stand in the way of effective co-operation and collaboration. It should be the duty of all trained thinkers, particularly men of science, on both sides of the water, to study these obstacles coolly and impartially. For only by knowing their nature may we hope to overcome them. Only by dispassionate study may we hope to reduce these barriers.

I say particularly men of science, for they realize more than many others the potentialities that lie hidden in the future. Men of science realize as many cannot the extent to which modern technology has diminished effective distances around this planet. They know, too, that the end of this revolution in transportation is not yet in sight. The world contracts before their eyes. To them dreams of new adventures and new conquests of the material universe wait for realization only on the sustained labour of free men. To-day, the men of science of Great Britain and the United States are working almost as one group with the purpose of improving instruments of war. Is it fantastic to hope that in the not too distant future the men of science of all free countries may be joined in effective action to improve, not instruments of war, but those of peace? I like to see in the present scientific liaison that runs through the centre of London, Ottawa and Washington a hopeful omen of a long period marked by the friendliest relations between the British Commonwealth of Nations and the United States. If this be so, our work foreshadows a time when professional talent in many diverse societies of free men will strive for effective co-operation to the end that we and our children may walk boldly along the paths of liberty and peace.

AGRICULTURE AFTER THE WAR

By SIR JOHN RUSSELL, F.R.S.

Director, Rothamsted Experimental Station

THE invention of the submarine has profoundly affected the development of British agriculture, bringing it out of its accustomed obscurity into a very high position both in the War of 1914–18 and in this War. British peace-time dietary is more varied and effective than that of any other country in Europe, but it requires so much land for its production—on the average some 1·6 acres per person—that the total area of agricultural land suffices only to provide 40 per cent of the nation's food. The remaining 60 per cent has to be imported, and it was brought in from almost all quarters of the world. This method of feeding the nation postulates peace and the smooth working of international trade, and it breaks down in war-time. Home production then becomes much more important, and the national dietary is changed so as to make less call on the land; in place of the 1·6 acres of peace-time, the aim is to get nearer to the 1·1 acres that suffice for the German dietary. Further, there is widespread recognition that British agriculture is a major industry, and that unless it is sufficiently prosperous to attract and retain a vigorous and intelligent body of farmers and farm workers, there will always be trouble in the country-side. Under the chastening influence of war, politicians and writers become very penitent about their past attitude to agriculture and full of good resolves for the future.

We are somewhat in this position now, and we passed through the same phase in the War of 1914–18. Then it was resolved that British agriculture really should be developed, and wages boards were set up to impose a minimum wage which would ensure the workers' efficiency and do away with the hardships which some of them had suffered. Prices were to be at such a level that these wages could be paid.

There arose the difficulty that has always proved oppressive and for which no satisfactory remedy has yet been put into operation. Agricultural produce can be raised very cheaply by peasants in almost any country in Europe and by farmers using ranching or other 'extensive' methods in some of the new countries, and trading organizations can collect it and bring it to our markets at very cheap rates. The peasant is, of course, poorly paid, but his standards are low, and the 'extensive' methods may be harmful and even destructive to the soil; but they answer for a time. In other producing countries where sound intensive methods were used, special arrangements were often made on the home market so as to enable the commodity to be sold cheaply on the English market. Finally, whenever a specially bountiful harvest had provided a large excess over the usual supply, this was put on to the British market as being the only one that would take it. In consequence the prices of agricultural produce here had no relation to the cost of production on farms in Great Britain, and moreover they were quite unpredictable, so that British farmers had no idea when they sowed their crops what prices they would receive for them. The only exceptions were milk and potatoes, of which there was little or no import, and a few commodities such as high-quality meat, malting barley, seeds and certain fruits and vegetables, for which a special demand existed.

For the rank and file of the farming profession there was no security, and most farmers adopted the traditional safeguard of laying down their land to grass and cutting down all expenditure; thereby reducing the outgoings to the point at which returns, though also greatly reduced, would balance them. Farmers put up the best fight they could; they lowered costs of production by reducing the numbers of their workers but increasing the output per head from the survivors, so that finally the average output per worker was equivalent to the feeding of seventeen persons, this being higher than in any European country. Some farmers went in for considerable mechanization, but this had its disadvantages. On one farm the new system reduced the cost of wheat-growing by nearly half. But while on the old system the farm had produced 630 cwt. of meat per annum, on on the new one it produced none. Much more serious: on the old system forty men had been regularly employed, on the new one only four were needed and the remaining thirty-six were 'released': and of these, twenty-two became a charge on public funds. Obviously one-sided arrangements of this sort are not desirable. The fall in area of arable land became so serious that steps had to be taken against it: these were in the nature of contracts, and unfortunately were called subsidies.

All history shows that British agriculture cannot stand up against the unrestricted imports of foodstuffs at low prices, and if farmers are left to solve the problem unaided no better way has yet been found than lowering the level of agricultural operations. It can safely be assumed that this same difficulty will arise after the present war, and that the same method of coping with it will be adopted unless a better one has in the meantime been adopted.

Fortunately a number of people are trying to design alternative solutions. During the War of 1914–18 it was thought that small holdings would solve the problem: the small man, it was said, would work with greater economy and be content with less reward than the large farmer and so might survive. But he did not, and although many small holdings were set up, an even larger number closed down, so that this solution does not appear to be general. Clearly some new proposal is now needed, and Sir Daniel Hall supplies this in his latest book*. He advocates large units, which would mean so much regrouping of the land, alterations of buildings and redistribution of implements and stock that the present landowners could not possibly undertake the task. He therefore suggests that the State should purchase the whole of the agricultural land of the country, that a commission should cut it up into units of suitable size, provide appropriate buildings and carry out the reclamations necessary, then hand the finished farms over to the Commissioners of Crown Lands, who would pass them on to land agents, who would let them to farmers. The proposal will certainly receive the serious consideration which Sir Daniel's distinguished authority requires.

An important reason for the failure of the promised development of agriculture after the War of 1914–18 was that no decision was ever reached as to the part that agriculture should play in the national life.

The prime need in any agricultural policy is to decide what proportion of our different foods we should aim at producing; and from what countries and in what amounts we should draw the foods that we propose to import. As the largest buyers of agricultural produce in the world, we are in a position to exert a very potent influence on post-war economy in a large number of countries, and our influence will be good if we work out a proper plan and stick to it.

Whatever agricultural systems are adopted the contract price method is essential now that wages are fixed by agricultural wages boards without reference to prices of produce. When adequate prices are assured it becomes possible to decide whether we should continue the classical system in which about 50 per cent of the arable land is in grain, 25 per cent in temporary clover and grass leys, and 25 per cent in root crops and potatoes, proportions which held generally right up to the War, or whether some more intensive systems should be adopted, such as that recommended by the Astor-Rowntree group, in which farmers aim at high quality and what one might call high potential: the protective foods, milk, fruit, eggs, vegetables and high-quality meat. These gain in value by being fresh, that is, by being produced locally: they employ more people per acre and give a larger output per acre than other kinds of produce.

---

* Reconstruction and the Land: an Approach to Farming in the National Interest. By Sir A. Daniel Hall. Pp. xi+287. (London: Macmillan and Co., Ltd., 1941.) 12*s*. 6*d*. net.

Account must also be taken of the part that agriculture can play in solving social problems such as unemployment and the rehabilitation of the unfit, and also of the vitally important problem of safety in war-time.

Science must always play an important part in agricultural development, though it needs careful management because of the wide difference in outlook between scientific workers and agriculturists. Agricultural operations are so dominated by weather and by other disturbing factors, including pests and diseases, that no rigid rules can be laid down. An experimental result can never have quite the same validity as in a chemical or physical laboratory. It may always be profoundly affected by some wholly unexpected and perhaps unobserved factor, and until it has been confirmed over a wide range of conditions it is liable to the suspicion that it may be abnormal. When all results are assembled they can be subjected to statistical analysis and an average obtained with its appropriate standard error, but it may not apply on any particular farm even though over a hundred farms it might hold good for a majority. Frequently the farmer has arrived at a general fund of knowledge about his own farm, which he is reluctant to disturb except on very convincing evidence. 'Good husbandry' is his ideal, and he firmly believes in its 'rules', even though some of them very inadequately express the facts. The agricultural departments of the colleges necessarily reflect this attitude: farmers and students alike are usually more interested in practice than in science and so more influenced by experience than by experiments: indeed not infrequently they are prepared to ignore or at least heavily discount experimental evidence if it does not fit in with established ideas. Their outlook on Nature is usually vitalistic, and special virtue is always supposed to reside in anything of organic origin as against substances of mineral or synthetic origin.

So a difference in outlook tends to arise between the agricultural research institutes and the agricultural community they are hoping to serve, and the difference is widened by the circumstance that the research institutes, if they are to keep their science at a serious level, have almost always to draw their staff from the science departments of the universities; usually the candidate who is otherwise most suitable has no rural background and no knowledge of agriculture; to acquire this is generally very difficult. It is necessary also to distinguish between the good research man and the good adviser, and to determine the place the adviser should have in the research institute. Broadly speaking, the good research man can see his problem, study it in full detail and find a solution, going on with the work until he has rounded it off properly and written it up for publication. But often it is not immediately useful for practical farming, though, of course, new knowledge is bound to find its place in agricultural science and practice. The good advisory officer can also see his problem and study it in detail; he, too, finds a solution, which may be of more immediate service on the farm than the scientific investigation. But he rarely goes beyond the stage of the interim report, so that his work is never rounded off and much of it never published, to the loss of public funds and the detriment of the juniors who also participated.

In the days when they were small, the research institutes necessarily kept close touch with the farming community and had to do both types of work: the individual members of the staff knew many farmers personally and well. As agricultural science has developed and expanded, it is the advisory officer rather than the research man that has had most to do with practical farming problems. This is in part the explanation of the curious decrying of science by some agricultural writers and the elevation into prominence of some of the mystical hypotheses of plant growth and human and animal nutrition which cannot be tested scientifically. These serious problems in the relation of science to agriculture require fuller study.

SCIENTIFIC CENTENARIES IN 1942

By ENGINEER CAPTAIN EDGAR C. SMITH, O.B.E., R.N.

SCATTERED through the coming year are days which will mark the centenaries of some of the most famous men of all time. In happier circumstances, it may be presumed that already arrangements would be in progress for the commemoration of some of these centenaries on an international scale. But more urgent tasks lie ahead. Yet it may, perhaps, be hoped that such events as the tercentenary of the death of Galileo, the tercentenary of the birth of Newton and the bicentenary of Halley will not be allowed to pass quite unnoticed. It is unnecessary to recall how the researches and discoveries of these great pioneers are closely interwoven, but it may, perhaps, be permitted to recall Rigaud's words regarding the publication of Newton's "Principia". In his essay on that immortal work Rigaud wrote: "Under the circumstances it is hardly possible to form a sufficient estimate of the immense obligation which the world owes in this respect to Halley, without whose great zeal, able management, unwearied perseverance, scientific attainments and disinterested generosity the Principia might never have been published."

When Halley died he had held the office of Astronomer Royal for some twenty years, having succeeded Flamsteed in 1720. His death took place on January 14, 1742, a few months before that of Abraham Sharp, who had furnished Flamsteed with instruments, and of whom Smeaton, in a report in the *Philosophical Transactions* in 1786, said that "I look upon Mr. Sharp as having been the first person that cut accurate and delicate divisions upon astronomical instruments".

Another interesting figure of those times, and one well known in Great Britain, was the Dutch mathematician Wilhelm Jacob 's Gravesande (1688–1742), the first professor of the University of Leyden to teach the Newtonian philosophy, and the author of a work on natural philosophy, Desagulier's translation of which was studied eagerly by James Watt as a boy of fifteen.

The men of science born in 1742 include the famous Swedish chemist Scheele, the German natural philosopher Lichtenberg and the unfortunate French chemist and inventor Nicolas Leblanc. When surgeon to the Duke of Orleans, Leblanc, to gain a prize offered by the Paris Academy of Sciences, set himself the problem of making soda from common salt. After several years he was rewarded with success, and with the aid of the Duke a factory was erected at St. Denis. Then came the French Revolution. The Duke was guillotined, the factory was confiscated and Leblanc forced to reveal his process. After much misery Leblanc, in 1806, died by his own hand. At one time his name was almost forgotten, but to-day his statue stands in the forecourt of the Conservatoire des Arts et Métiers in Paris.

Coming down to 1842 the list lengthens, but it is proposed to refer to only a few of the more important men. In April of that year the British surgeon, Sir Charles Bell, died suddenly at the age of sixty-eight; on September 6 the Belgian chemist Jean Baptiste van Mons passed away at Louvain, having done much to spread a knowledge of the discoveries of Lavoisier and his successors, and on September 21 the British mathematician Sir James Ivory, Copley medallist in 1814, died in Hampstead. The month of February 1842 saw the birth of the French astronomer Camille Flammarion (died, 1925), the month of April the birth of the German astronomer Hermann Carl Vogel (died, 1907). Carl von Linde, the German pioneer of refrigeration, was born in June 1842; the German chemist Albert Ladenburg, in July. Sir William Tilden, Sir James Dewar and Lord Rayleigh were all born in the latter part of 1842, as were also the Norwegian mathematician Marius Sophia Lie, For. Mem. R.S., and the Russian chemist, Nicolai Alexandrovich Menschutkin, one of the outstanding contemporaries of Mendeléeff. Lie died in 1899, Menschutkin in 1907. A memoir of the latter by Tilden appeared in the *Journal of the Chemical Society* in 1911.

OBITUARIES

Prof. Rudolf Schoenheimer

THE death of Rudolf Schoenheimer at the early age of forty-three has removed from our midst a biochemist of outstanding ability. His work, characterized always by originality of conception, has opened up a new, and most fertile, field in biochemistry.

Schoenheimer was born in Berlin in 1898 and he received his M.D. there in 1922. He was associated with the University of Freiburg and became head of its Department of Pathological Chemistry in 1931. He left Germany in 1933 to take up a position as assistant, and later as associate, professor of biochemistry in the College of Physicians and Surgeons, Columbia University. He held this position at the time of his death in September 1941.

Schoenheimer's work, until he went finally to the United States, was concerned primarily with the metabolism of cholesterol. He continued his studies on cholesterol for a few years and in 1934 he commenced his work on the application of stable isotopes to the study of intermediary metabolism. During the following seven years Schoenheimer, usually in co-operation with his colleague D. Rittenberg, developed this new experimental approach to problems of biochemistry.

Much of our knowledge of intermediary metabolism depends on an analysis of the products formed after the administration to an animal of substances which may or may not be normal metabolites. The method has been extended to the use of intact isolated organs (by perfusion techniques) or of surviving tissue slices. Much valuable information has been and is still being obtained by work carried out in this manner. It is recognized, however, that this method of investigation has definite limitations. Administration to the body of relatively large quantities of even normal metabolites may upset the normal balance of events and call forth changes which do not reflect the normal quantitative relationships. Administration of substances, labelled with halogen, phenyl or other groups to facilitate the chemical examination of intermediates in the process of breakdown of the parent substances, involves the use of compounds having different chemical and physical properties from those of normal substrates and metabolites. Such substances, foreign to the body, may be treated, in certain respects, differently from normal substances. Yet the elucidation of the intermediate steps in the course of breakdown of normal substrates in the body or in the living cell represents one of the most important and formidable problems in biochemistry.

The introduction into a metabolite of isotopes of one or more of its elements brings about little or no change in its physical or chemical properties, and hence it is not to be expected that the animal will be able to differentiate between a normal metabolite and one containing isotopes of its elements. Experimental evidence exists which supports this conclusion. Since it is now possible to distinguish isotopes and to estimate them in relatively small quantities and in high dilutions, it is obvious that the use of molecules containing isotopes places a new and most powerful weapon in the hands of the biochemist.

The first to realize the importance of isotopes for biological investigations was von Hevesy, who studied phosphorus metabolism, using radioactive phosphorus. Radioactive isotopes of hydrogen and nitrogen, however, the migrations of which in the body form so important an aspect of intermediary metabolism, were not known, at the time of Schoenheimer's work, with a half-life long enough to permit their use in metabolism experiments. It was necessary to use stable isotopes concentrated from the natural mixtures. Urey, by devising methods of isotope fractionation, made it possible to use such isotopes in metabolism work.

The first series of experiments of Schoenheimer and his colleagues (*J. Biol. Chem.*, 1935–38) was concerned with the use of deuterium. They employed two methods of attack. They administered heavy water to animals over a certain period and then estimated the stable deuterium in the different organic constituents of the body. This gave information on the nature of the substances utilizing hydrogen of the body fluids themselves. They synthesized and administered organic compounds containing deuterium and followed up the fate of the isotope. This gave information on the mode of breakdown of the labelled organic compound.

They were able to show, on feeding fats containing deuterium, that the major part (even if administered in relatively small amounts) is deposited in fat depots prior to utilization. They showed that desaturation of fats, as, for example, the transformation of stearic acid into oleic acid, and that the conversion of stearic acid into palmitic acid, are processes definitely occurring in the animal body. They showed that reversible saturation and desaturation of fats are normal metabolic changes. Schoenheimer and his colleagues further demonstrated, by feeding experiments with deuterobutyric and caproic acids, that these short-chain fatty acids are completely burned in the body and not used for fat formation. They followed fatty acid development in the embryo and in the adult animal and investigated sterol metabolism and synthesis. In all these investigations they were faced with serious difficulties, having to devise methods of synthesis of isotope-containing compounds and to cope with the problem of the stability of the carbon-bound hydrogen *in vivo*.

Schoenheimer and his colleagues turned their attention to the study of protein metabolism using ^{15}N as the isotopic label (*J. Biol. Chem.*, 1939–41). This isotope was estimated by means of the mass-spectrograph. They showed that isotopes ^{14}N and ^{15}N are treated by the body indiscriminately in anabolic and catabolic processes. They found that administered glycine (marked with ^{15}N) may be used partly for hippuric acid synthesis, that animals fed with isotopic ammonium citrate form proteins, the constituent amino acids of which, with the exception of lysine, contain ^{15}N. This made it evident that amino acids can be built up in the body from dietary ammonia. The fate of amino acids such as tyrosine containing ^{15}N, after ingestion by an animal, was investigated and it was shown that part of the ^{15}N is transferred to various other amino acids in the proteins of the animal. The experiments indicated that in a normal full-grown and healthy animal, kept on a normal diet, the nitrogen of the dietary amino acid may only partly be excreted in the urine, the rest being retained in the protein of the animal with a corresponding excretion of tissue nitrogen. The exceptional property of lysine, among the amino acids, in resisting the introduction into its molecule of ^{15}N, after the ingestion by an animal of isotopic nitrogen, was demonstrated. Apparently lysine is not involved in the reversible shift of amino groups, which seems to be a prominent feature of nitrogen metabolism of the body.

It is clear that metabolism work involving the use of isotopes has just begun, and the significant results already obtained justify a great extension of the work. It is indeed a tragedy, and a most serious loss to biological science, that Schoenheimer should have been cut off at so early an age from those pioneer investigations the future of which is so full of promise.

J. H. QUASTEL.

Dr. W. Steiner

DR. WERNER STEINER, born 1896 at Cologne, died after a brief illness on September 10 at Durham. From 1926 onwards he was Prof. M. Bodenstein's assistant in the Institute of Physical Chemistry at Berlin and in charge there of the teaching and research work in spectroscopy. He published some thirty valuable papers on this and related subjects, several of them in English journals. After leaving Germany in 1933 he worked for a while on similar lines at Cambridge in the laboratories of the late Prof. T. M. Lowry. In 1936 he accepted the position of a science master at the Gordonstoun School in Morayshire, and in January 1941 at the Durham School. Here, as well as in his University career, he gave of his best. Besides science his main interest was divinity, and his last contribution was to a theological journal.

F. A. PANETH.

WE regret to announce the following deaths:

Mr. F. A. Leete, C.I.E., lately chief conservator of forests, Burma, on December 11.

Prof. J. Wilson, formerly professor of agriculture in the Royal College of Science, Dublin, on December 9, aged seventy-nine.

NEWS and VIEWS

Great Britain and the United States

THE Association of Scientific Workers has, through its Social Relations Committee, recently sent the following message to American men of science: "We British scientists, engineers and technicians organised in the Association of Scientific Workers send our greetings to our colleagues in the United States of America. . . . With the combined might and resources of the U.S.A., the U.S.S.R., China and the British Commonwealth of Nations, ultimate victory is certain. We are nevertheless faced by a powerful and desperate combination of powers. They too have large resources and the advantage of having planned for war many years before actual fighting started. Their scientists have been concerned with the specific problems of warfare and supply for many years longer than we have. We must make up this leeway. But we can do more than that. We, the scientists in the Allied countries, can by pooling our ideas, technical skill and cognate information, play in concert a most vital part in the common effort. . . . We are happy to recall the very close bonds which have united men of science of our two countries in the past. Many of us have personal friends among you. We have worked in your great laboratories; you have worked in ours. This interchange will prove to be most valuable in the present situation. We have as well the terrific advantage of a common language, and, to a large extent, of a common cultural heritage. But we still have a lot to learn from each other and from our Soviet colleagues. By helping each other without stint, we shall help ourselves and we shall be laying the foundations of a truly international scientific commonwealth. American, Soviet and British scientists have the responsibility of preserving the scientific heritage of the whole world against the barbarism and obscurantism of Fascist 'ideology'. We shall do it, and we shall enrich and strengthen it by so doing. Our most sincere and best wishes to you."

The Empire Bond

YET another sign, if such be needed, of the intangible bond which links together the several members of the British Commonwealth of Nations is provided by the letter printed on p. 21 of this issue, from the honorary secretary of the Australian National Research Council. In this letter, Dr. H. R. Carne offers hospitality in Australian laboratories to scientific workers in Great Britain who are unable to make any direct contribution to the war effort. Not only scientific workers in Great Britain, but also the many students from other parts of the Empire who would normally be proceeding to postgraduate courses or research work in this country but are prevented by present circumstances, are offered an invitation to utilize the universities and research institutes of Australia, to carry on their work. While it is unlikely that many in Great Britain will be able —or will indeed wish—to leave the country at the present time, scientific workers everywhere will appreciate the friendly spirit in which the invitation has been given, and will wish to thank their Australian colleagues for the very practical form which their concern about the influence of war-time conditions on research has taken. Although the outbreak of war in the Pacific may make it necessary for Australian institutions to modify their offer (Dr. Carne's letter was dated September 19), the fact that it was made by a country already deeply involved in the War is worthy of record.

Malayan Wild-Life

THE war in Malaya is no doubt interfering with the very interesting wild-life of that region, and the observations that have so long centred upon it. Robinson and Chasen's work on the birds of Malaya describes such interesting items as the breeding habits of the edible-nest swiftlets, the gorgeous sunbirds and the spider-hunters. Malaya has some seven hundred birds including about forty game birds and pigeons. An earlier official publication on the birds of Singapore gives a list of more than a hundred species, including eleven of the sixteen Malayan kingfishers and many interesting doves, hornbills, the vividly coloured little red and orange flower-peckers that haunt the tree-tops, the rollers, the bee-eaters and several swifts. Many species well known in Britain are winter visitors or migrants from northern Asia, including snipe, golden plover, redshank, turnstones, greenshank, and grey plover. The roseate and gull-billed terns are regular birds of Singapore island, the Kentish plover nests on the sandy shores and herons and white egrets fish the marshes. The fishing owl is a very common bird. The "Handbook to British Malaya" states that the fauna of British Malaya is excelled in number of species only in parts of South America. The one-horned Javan rhinoceros is almost extinct, and the common rhinoceros, like the Malayan elephant, has been much persecuted for ivory. The ancient Malayan tapir survives, but the Malayan bison or seladand is almost extinct in certain districts. There are several deer, and the curious serow or goat antelope is in the remoter country. The Malaya tiger is smaller than the Indian, while monkeys and apes include the curious nocturnal slow loris and also orangs, which have often been collected for European zoos. Malaya is the metropolis of the squirrels and there are more than sixty bats, including the great flying fox or keluan with a wing span of nearly five feet, which haunts the coastal mangroves.

As well as the big game hunting, the snipe-shooting and pigeon-shooting are among the best in the world, but collectors have also been attracted to Malaya for fauna and flora. Corbett and Pendlebury's 1934 work on the butterflies of Malaya records more than eight hundred species. There are probably a quarter of a million insects including more than a thousand butterflies in this region, with many of the swallowtail family. There are the famous birdwing butterflies which often feed with their forewings fluttering and their hindwings kept fairly still. One of the most striking butterflies in the world is Rajah Brook's birdwing, *Papila brookiana*, with a wing span of 6¾ in., which was discovered by Dr. R. A. Wallace in Borneo. The sex ratio is such that the female is about one to every thousand males. The long-tailed blue butterfly of the English list also occurs here, and there are many skippers. There is also the giant atlas moth. Reptiles are not quite so evident as in India and Australia, but crocodiles are numerous, and Russell's viper and other deadly Indian snakes are found here too ; also the largest living snake, the king cobra or hamadryad, with a recorded length of 18 ft. 6 in. There are many lizards, turtles and tortoises, including the flying lizard. There are some three hundred fishes in the rivers, including catfish and carp.

The flora of Malaya has been written up by H. N. Ridley, while from a horticultural point of view, the Western world has sent many collectors for its orchids. There are twenty-eight Vitis plants, sixteen Vacciniums and some seven hundred orchids and wild forms of many Western garden favourites like *Canna orientalis.* There are twenty-one Dracænes, thirteen Carex, five Scirpus, three Lemna and the tiny Waffia's microscopic flowers in the ditches and wells. Some plants familiar to British botanists include the common reed *Phragmites communis* on river banks, the chickweed, *Stellaria media,* as a weed of cultivation and the dandelion *Taraxacum Dens-Leonis,* an "escape' on the Penang Hill. The Malayan flora totals some nine thousand species, and of more than three hundred trees in which the tall Dipterocarpaceæ predominate, some half are peculiar to the Peninsula. Lianas, rhododendrons, epiphytes and small palms are characteristic.

Television in Colour and Stereoscopic Relief

HITHERTO, television has been confined to flat pictures. In a press demonstration on December 18, Mr. J. L. Baird demonstrated stereoscopic relief in combination with television in colour. Mr. Baird states that his first experiment in this direction was applied to his 600-line two-colour apparatus. The red image was made to 'view' the scene from a slightly different angle from the blue, so that the red and blue images constituted a stereoscopic pair, the receiving screen being viewed through glasses fitted with red and blue filters as in the anaglyph process. This, while simple, had the disadvantage that it was necessary to wear glasses and that, as the colour phenomenon was used to effect the change over from the right to the left eye, neither the colours nor the stereoscopy could ever be properly rendered. So far the object in mind had been to produce a system capable of being transmitted through the existing channels available to the B.B.C., but in an endeavour to produce as perfect a result as possible, it was decided to produce an entirely experimental apparatus regardless of existing practical limitations.

In the apparatus now demonstrated by Mr. Baird, the frame frequency has been increased from 50/sec. to 150/sec., the scanning altered to a field of 100 lines interlaced five times to give a 500-line picture, successive 100-line frames being coloured green, red and blue. At the transmitter a cathode ray tube is used in conjunction with photo-electric cells, the moving light spot being projected upon the scene transmitted. In front of the projecting lens a mirror device consisting of four mirrors at right angles splits the emerging light beam into two paths separated by a space equal to the separation of the human eye. By means of a revolving shutter the scene is scanned by each beam alternately, so that images corresponding to the right and left eye are transmitted in rapid sequence. Before passing through the shutter disk the light passes through a rotating disk with blue, red and green filters. Thus superimposed red, blue and green pictures blending to give a picture with full natural colours are transmitted for left and right eye alternately. At the receiver the coloured stereoscopic pairs of images are reproduced in sequence and projected upon a field lens, alternate halves of the projecting lens being exposed by means of a rotating shutter, the image of the shutter being projected upon the eye of the viewer so that his left and right eyes are presented alternately with the left and right images, the combined effect being a stereoscopic image in full natural colours.

Poverty and Malnutrition in South Africa

EVIDENCE given to the Industrial and Agricultural Requirements Commission by Dr. T. W. B. Osborn on March 17, 1941, has now been published under the title "Remedies for Poverty and Malnutrition in South Africa". (Pp. iii+22. Johannesburg : Central News Agency, Ltd., 1941. 2*s*. 6*d*.). Dr. Osborn, pointing out that the mines managements of the Rand have already convinced themselves that it pays to put their native labour force on a well-balanced ration, emphasizes the significance of the prevention of malnutrition in regard to infantile mortality and general physique among the Bantu. The potential production of foodstuffs in South Africa is considered more than sufficient to give each member of the community an ample balanced diet. Distribution is the major problem—getting the right food to the people, by increasing their purchasing power, subsidizing consumption, or free distribution. He criticizes milling practice in the cereal industry and asserts that it is essential that the germ of the wheat should go back into refined flour and mealie meal. The conversion of more skim milk into food for human consumption, development of the margarine industry on the grounds of price, in spite of the butter surplus, encouragement of soya bean growing, of the consumption of meat, fish and peanuts by the poorer sections of the community, and of the use of vegetables and fruit rich in vitamin C, such as guavas and red peppers, are also advocated.

The consumption of these foods so as to eliminate malnutrition should be encouraged within the present economic framework by a system of subsidies, preferably a combination of free distribution, subsidy to the consumer and subsidy to commerce. Dr. Osborn cites for example a scheme to encourage the use of mealie meal containing 5 per cent of soya bean meal, and then discusses the long-term solution of the problem of removing poverty in the midst of plenty. This means raising the general standard of living and making the economic struggle for existence less intense and ruthless. The final aims are to induce the maximum of economic efficiency, economic equity and personal freedom. Raising wages and reducing costs are not general remedies. They must be supported by measures to stimulate investment and consumption, and Dr. Osborn stresses the value of more generous State provision for sickness, old age and child welfare, the endowment of research, public works, consumer subsidies and the encouragement of drama and the arts. Means to check inflation are essential as well as the control of land values, the share market and overseas influences. Economic self-sufficiency he considers is not necessarily retrograde, but he emphasizes the necessity of unorthodox methods and also of safeguards against bureaucracy in the economic planning required.

The Forests of India

IT would perhaps be difficult to find stronger evidence of the changes which have taken place in the management of the forests of India and the almost complete manner in which the Secretary of State for India, and the Central Government of India itself, are dissociating themselves from their administration, than is provided by the Inspector-General of Forest's Quinquennial Review ending March 31, 1939. (Ann. Return of Statistics relating to Forest Administration in British India for 1938–39 and Quinquennial Review ending March 31, 1939. Govt. of India Press, Calcutta, 1941.) For well over half a century the forests of India, their protection and improvement (and incidentally the increasing revenue they yielded), had formed a personal pre-occupation of successive Secretaries of State for India and (with that spur) of successive Governors-General and Viceroys. With increasing efficiency in management it became no longer possible for an inspector-general to portray in an annual report, kept within official requirements of space, the work being carried out throughout India and Burma. The latter was therefore reduced to tabular statements of statistics only, whilst a quinquennial report gave an eye-picture of the progress in management and the position of the forest estate.

It can now be realized that these reports have the very highest value in the light of the new position brought about by the Government of India Act, 1935, under which the forests are transferred to the individual provinces. The India Forest Service at present numbers 219 officers, of whom 163 were recruited at home direct to the Service. Gradually, with the retirement of these officers, the forests and their management will become purely the affair of the various provincial Governments. Even the senior administrative appointments, conservators and chief conservators in provinces, will no longer, it is said, be made by the Central Government. The Government of India still maintains an Inspector-General of Forests, shorn of all power, who is at the same time president of the Forest Research Institute and College at Dehra Dun. At the College the officers for the new 'Superior Forest Services' of the individual provinces are to be trained. The Inspector-General is permitted to visit, on invitation, the various provinces, but his reports on such visits are purely advisory. In fact, as the Quinquennial Report for 1934–35 to 1938–39 indicates, the chief position in forestry administration of the Inspector-General at the present time is his occupancy of the presidentship of the Research Institute. Out of 24 pages in this report less than six are devoted to describing work of purely forest management, and the remainder to forestry research work. Yet this latter is dealt with very fully in the annual reports of the Research Institute.

The annual revenue from the great forest estate of India and Burma for the year 1936–37 (before the separation of the latter) amounted to Rs.4,38,07,019, or well over three million pounds sterling. In addition nearly half a million pounds sterling of forest produce is given away free or at reduced rates. Many senior men with long experience in the administration of this great forest estate, the correct management and maintenance of which is vital to India as a whole, view with concern and distrust the devolution of their powers and responsibility by the Secretary of State and Governor-General.

An Index to Horticultural Research

THE availability of research results of a purely horticultural character has been greatly increased by the publication of *Horticultural Abstracts* by the Imperial Bureau of Horticulture and Plantation Crops, East Malling, Kent. Mr. D. Akenhead, deputy director of the Bureau, has now compiled an index to the first ten volumes, covering the period 1931–40 (Sept. 1941, 160 pp., 25*s*.). The volume contains a subject index and an alphabetical list of authors; it is world-wide in scope, and demonstrates the prosecution of an enormous volume of horticultural research during the decade it reviews. Greatest use of the index demands its relation to the journal which it serves, but the research worker can see from the present volume whether any work in his particular line has been reported. Detail is quite adequate for modern needs, for a reference can be found to apple sauce as well as to *Rhizopus arrhizus* rot of that crop, and to the utilization of waste potatoes, in addition to rubidium absorption in potato disks. The subject index is compiled with the different crop plants as the chief points of interest. The volume certainly achieves its expressed object of making information as available to the English-speaking horticultural worker as possible.

Health of Palestine

ACCORDING to the report for 1939 recently published by the Department of Health in Palestine, the country was so much disturbed by political strife in that year as to prevent development of health work. The health of the people, however, was remarkably good, and there were no important epidemics. The recorded incidence of infectious diseases was the lowest for many years, and the death-rate from them half that of 1931. The total population numbered 1,501,698, of which 60 per cent were Moslems, 30 per cent Jews and 10 per cent Christians and others. The birth-rate was twice as high among Moslems (46·4 per cent) as among the Jews (23·0 per cent). Both rates were falling, but that of the Jews more rapidly than that of the Moslems. The death-rate of the Moslems was much more than double that of the Jews. Infantile mortality was 121·5 per 1,000 live births among the Moslems and 54 among the Jews; for Christians the rate was 101. These rates were the lowest ever recorded and showed a sharp decline from previous years. Of the various diseases diarrhœa caused 1,336 deaths and pneumonia 1,258, then in order of frequency came heart disease 617, cancer 364, cerebral hæmorrhage 311, and nephritis 276. 3,394 cases of malaria were reported with 15 deaths, 1,235 cases of typhoid with 134 deaths, and 175 cases of paratyphoid with 2 deaths. There has been no increase in tuberculosis in the last ten years. Ophthalmias are a formidable problem.

Piezo-Electro Crystal Filters

A BRIEF outline of the history of the crystal filter has been published by J. E. Benson (*A.W.A. Tech. Rev.*, 5, 191; 1941). The earliest application of piezo-electric crystals to frequency-selective circuits appears to have been made in 1920 by W. G. Cady, whose patent describes the behaviour of piezoelectric elements near resonance and their consequent use in the selection and measurement of high frequencies. L. Ezpenschied (Jan. 3, 1927) described the quartz-crystal band-pass filter having recurrent sections. This was followed by W. A. Marrison's patent (June 7, 1927) for a balanced crystal-gate filter designed for sharp response at a single frequency. In the same year, C. W. Hansell developed a similar bridge-balanced system, in which the parallel capacity of the crystal was balanced out of an equal capacity supplied from the input circuit in opposite phase to the crystal. Single-frequency rejection filters of the *T*-section type having a piezo-electric element in the shunt arm were described at about the same time by I. F. Byrnes. J. Robinson's stenode radiostat using a balanced crystal-filter circuit appeared in 1929.

Recent Earthquakes

ACCORDING to a radio message from Tokyo, the largest earthquake since 1930 shook southern Formosa on December 17. The epicentre is likely to have been near the town of Kagi around which most of the damage was done. Seventy-seven people were seriously injured and eighty-seven slightly hurt when 612 houses were destroyed and 918 badly damaged. Railway and telephone communications were temporarily severed. On the same day a violent earthquake occurred in the Mughla district of south-western Anatolia in Turkey. Damage was done to about eight hundred houses and a hospital, but only a few persons were injured. On December 20 an earthquake of moderate intensity shook Quetta. The shock lasted, according to human perception, for about ten seconds and was accompanied by a low rumbling sound. No damage has been reported, probably due to the new town having been built according to earthquake-proof design.

Institute of Physics Planning Committee

THE Board of the Institute of Physics has appointed a planning committee with the following terms of reference: "To watch and to advise the Board on matters affecting Physics and Physicists, including their education and training, and on post-war planning." The constitution of the Committee, which has power to co-opt, is as follows: Sir Lawrence Bragg, Prof. J. A. Crowther, Mr. E. R. Davies, Dr. H. Lowery, Major C. E. S. Phillips, Dr. C. Sykes, Dr. F. C. Toy. At the request of the Board the Committee will proceed at once to consider certain matters concerning the education and training of physicists. Close contact will be maintained with the participating societies of the Institute, namely the British Institute of Radiology, the Faraday Society, the Physical Society, and the Royal Meteorological Society, as well as with other bodies concerned with the application of physics to industry.

Announcements

PROF. HENRY NORRIS RUSSELL, research professor of astronomy at the University of Princeton, has been elected to an honorary fellowship at King's College, Cambridge. Prof. Russell, who is the doyen of American astronomers, graduated as Ph.D. at Princeton, after which he entered King's College, Cambridge, as an advanced student in 1902, and was in residence at Cambridge for three years. During that time he carried out research in collaboration with Mr. A. R. Hinks, now secretary of the Royal Geographical Society, upon parallax, and the methods they developed have become standard. This no doubt was a first step on the way to some of Prof. Russell's most notable work.

THE Harrison Memorial Prize, which is awarded by a selection committee consisting of the presidents of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry and the Pharmaceutical Society, has been awarded for 1941 to Dr. Henry Norman Rydon. This prize is given to a chemist of either sex who is a natural-born British subject, not more than thirty years of age, who, in the opinion of the selection committee, shall during the previous five years have conducted the most meritorious and promising original investigations in chemistry. The Prize is to be regarded as an exceptional distinction to commemorate an exceptional man.

THE Town and Country Planning Association has arranged a series of fortnightly lunch-time meetings at 1.20 on "Post-War Reconstruction", beginning on January 8, at the Dome Lounge, Messrs. Dickins and Jones, 224 Regent Street, London, W.1. Admission is by ticket obtainable from the Association. The first meeting will be addressed by Mr. George Hicks, parliamentary secretary to the Ministry of Works and Buildings, who will discuss the part the Ministry can take in reconstruction.

REFERRING to the obituary notice of Mr. R. T. Baker in NATURE of December 13, p. 718, Prof. John Read writes that Mr. Baker died at Cheltenham, New South Wales, on July 14, aged eighty-six years.

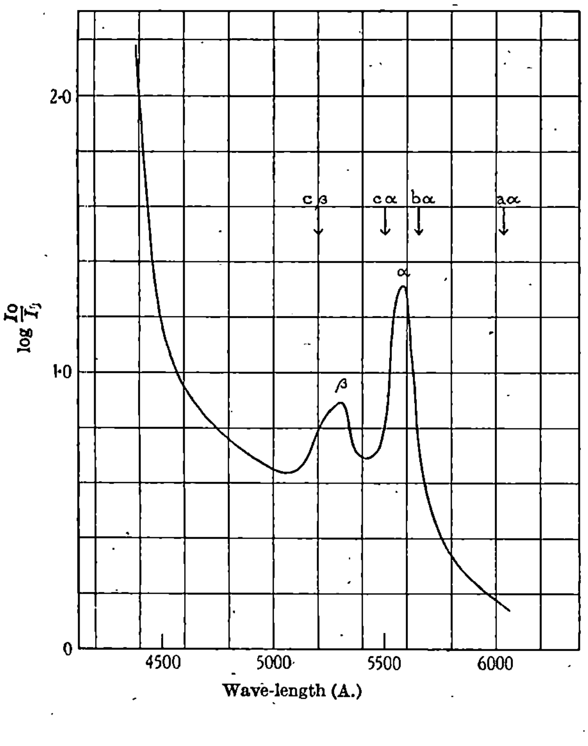
LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

A New Soluble Cytochrome Component from Yeast

HITHERTO cytochrome *c* is the only component of cytochrome which has been obtained in solution, the others being attached to the insoluble parts of the cell structure.

During the purification and concentration of the lactic dehydrogenase of yeast, as described in a future communication, we have obtained a new cytochrome which is extremely soluble in water. The positions of the bands of its absorption spectrum do not correspond with those of any cytochrome component known hitherto. The new component appears to be present in yeast in amounts too small for its detection by direct spectroscopic observation of the yeast cells ; but its spectrum becomes visible on removal of other coloured substances and concentration. We have obtained it in strong solution, red in colour, and free from other cytochromes. Its absorption spectrum in the reduced state, as determined in a Hilger-Nutting spectrophotometer, is shown in the accompanying graph, in which the positions of the bands of cytochromes *a*, *b* and *c*, as ordinarily seen in yeast, are also indicated. Its α band is situated at 5570 A., between the α bands of cytochrome *c* (5500 A.) and cytochrome *b* (5650 A.) ; the β band, which is unsymmetrical, has its peak at 5300 A. If a trace of cytochrome *c* is added, a distinct space can be seen between the α bands of the two cytochromes. In liquid-air the bands become much sharper ; the α band then appears double. The new component, unlike cytochrome *c*, is somewhat autoxidizable, and its bands disappear on shaking with air.



The spectrum is clearly that of a hæmochromogen. This hæmochromogen does not combine with carbon monoxide in neutral solution, and in this respect it resembles cytochromes *a*, *b* and *c*. On denaturation with dilute sodium hydroxide and addition of pyridine and hyposulphite, it is converted into pyridine hæmochromogen, with absorption bands identical with those of pyridine protohæmochromogen. The pigment, therefore, has a protohæmatin prosthetic group, like cytochrome *b* and unlike cytochromes *a* and *c*. By converting the pigment into its pyridine hæmochromogen and comparison with standard hæmochromogen solutions by the spectroscopic method described by Keilin[1], its concentration may be estimated with great accuracy. This makes it possible to calculate the absorption coefficient, which for the α band is found to be $\beta_{5570} = 0{\cdot}4 \times 10^8$ cm.^{2}/gm. atom Fe. The new cytochrome resembles cytochrome *b* not only in the nature of its prosthetic group, but also in being autoxidizable to some extent in neutral solutions. In order to avoid confusion with other hæmatin compounds, we suggest that it should be called cytochrome b_2.

Owing to the impossibility of obtaining Delft yeast, we have not been able to study the catalytic properties of cytochrome b_2 in detail. We have, however, found that it is not capable of replacing the substance[2] linking the succinic system with cytochrome *c* which is destroyed at *p*H 5, and which it has been suggested[3] might be cytochrome *b* or a hitherto unrecognized component. The identity of cytochrome b_2 with the yeast lactic dehydrogenase is discussed in a future communication.

X-Ray Study of the Elastic Constants of Metals

IN a recent letter[1] we showed that the diffuse X-ray reflections from single crystals of alkali metals are related to the elastic constants in just the way predicted by the Waller theory[2], as interpreted and applied by Jahn[3]. We are now able to give data for sodium which will illustrate this more conclusively.

The figures represent the intensity of diffuse reflecting power on the surface of a sphere surrounding the reciprocal lattice point (*hkl*), in the direction [*pqr*], as calculated from Jahn's formula. The observed intensities are derived from visual estimation on a series of Laue photographs taken at degree intervals, in various crystal orientations, the range of each set of photographs being sufficient to cover the entire observable reflecting region for each plane. Allowance has been made for the usual factors which affect the normal reflexions (structure factor, atomic scattering factor, factors involving the crystal and film positions relative to the incident beam), and which also, of course, affect the diffuse reflexions.

	Calculated intensities:				Observed intensities:			
± [*pqr*] (*hkl*)	(002)	(110)	(112)	(222)	(002)	(110)	(112)	(222)
[100]	24	22	24	23	—	—	—	—
[010]	24	22	24	23	—	—	—	—
[001]	19	24	21	23	—	—	—	—
[110]	24	11	20	16	—	—	—	—
$[1\bar{1}0]$	24	165	71	141	—	V.S.	M.	S.
[101]	88	56	30	16	M.S.	M.	W.	—
$[10\bar{1}]$	88	56	133	141	M.S.	M.	S.	S.
[011]	88	56	30	16	M.S.	M.	W.	—
$[01\bar{1}]$	88	56	133	141	M.S.	M.	S.	S.

Sodium single crystals are very soft and elastically anisotropic; they are body-centred cubic in structure. Lead single crystals are also soft and are anisotropic in the same sense ($c_{11}-c_{12} < 2c_{44}$), although the shear constant c_{44} is much smaller relative to the compressibility ($c_{11} + 2c_{12}$); but they are face-centred cubic in structure. Diffuse reflexion photographs (which are particularly good for large angles of incidence, on account of the slow decrease of the atomic scattering factor) show that the reflecting regions in reciprocal space are similar to those found for sodium, although the intensity 'spikes' are less pronounced. At low temperatures the diffuse reflexions almost disappear, but the Laue spots become much more numerous and the background clearer.

Tungsten crystallizes, like sodium, with a body-centred cubic structure, but it is elastically isotropic ($c_{11}-c_{12} = 2c_{44}$) and the elastic constants are large.

	c_{11}	c_{12}	c_{44}	$c_{11}-c_{12}$	$c_{11}+2c_{12}$	($\times 10^{11}$dynes/cm.^{2})
Na	0·52	0·40	0·41	0·12	1·32	(4)
Pb	4·77	4·03	1·44	0·74	12·83	(5)
W	51·3	20·6	15·3	30·7	92·5	(6)
	50·1	19·8	15·1	30·3	89·7	(7)

For tungsten, the Jahn formula predicts small, elliptical diffuse spots which should disappear at a very small angular distance from the Bragg position. This is exactly what we find. The diffuse spots are smaller than the Laue spots, and disappear at $\theta_B \pm 2°$; there are none of the detailed, persistent groups of spots and streaks (some of which extend right across the Brillouin zone boundaries) that are found for both sodium and lead. A rough calculation, which is in good qualitative agreement with our observation, indicates that the tungsten diffuse reflexion should be about $\frac{1}{30}$, and that of lead about $\frac{1}{2}$, as intense as the diffuse reflexion from sodium, for the first observed order from (110) planes.

The thermal theory predicts that the relation of diffuse to normal (Bragg) reflecting power for any set of planes should be governed by the actual values of the elastic constants and not primarily by the crystal structure. In our opinion, this is proved by the above experiments on single crystals of metals.

A Reversible Discharge Tube

R. W. Wood[1] has described an interesting discharge tube which could be made to exhibit "either the spectrum of atomic hydrogen or molecular oxygen at will" on excitation by a high-frequency discharge. In the course of investigations on the spectra of gases excited by high-frequency discharge, we have prepared a discharge tube which has an analogous behaviour and can be made to show either the air spectrum or hydrogen spectrum as desired. The fundamental difference between the two tubes, however, is that under the discharge hydrogen is suppressed by oxygen in Wood's tube, whereas here, hydrogen suppresses air.

The discharge tube, which has a quartz window and aluminium electrodes, was sealed off the evacuation apparatus after being repeatedly washed by hydrogen. The spectrogram taken soon afterwards showed only the spectra of hydrogen, in particular a very intense development of the well-known continuous spectrum of hydrogen. The tube was excited by high-frequency discharge. On standing for a few days the tube, on similar excitation, showed only nitrogen bands in the visible, clearly due to traces of residual air, and there was no trace of hydrogen. On continued excitation, however, hydrogen gradually appeared, nitrogen got weaker and in a couple of hours the tube showed nothing but hydrogen, nitrogen being suppressed under the discharge. The continuous spectrum of hydrogen was found to be considerably weakened in intensity while the atomic spectrum was very prominent, due, no doubt, to the absorption of hydrogen by the walls of the tube resulting in a gradual 'clean up'.

On cutting off the discharge and allowing the tube to rest for some period, the same series of phenomena can be repeated. Most of the hydrogen appears to be confined to the electrodes, for it has been possible so to excite the tube with external electrodes that, by omitting the internal electrodes from the path of discharge, the tube shows only the spectrum of air for any length of time.

Psycho-Physical Significance of the Dissipation Coefficient of Soft Materials

In an earlier communication[1] we raised the question of the significance of the dissipation coefficient (k) of soft materials, which we measure by compressing cylinders under loads compensated to ensure constant shear stress (S). For materials the firmness (ψ) of which is independent of stress, k is defined by an equation of the Nutting type[2]

$$\psi = S\sigma^{-1}t^k,$$

where σ is shear strain and t is time.

Broome and Bilmes have shown[3] that k is also given by the ratio of mean to differential viscosity ($S/\frac{\sigma}{t} \div S/\frac{\partial\sigma}{\partial t}$) and, for relaxation at constant strain, differentiation shows that the Maxwell relaxation time will vary as a power ($1/k$) of the stress.

In order to establish the psycho-physical significance of k, we have given pairs of cylinders to groups of ten subjects who, squeezing the cylinders under controlled conditions, were asked to decide which was the firmer of each pair, the squeezing being timed to take ½, 1, 2 and 4 sec. respectively. When a standard bitumen (viscosity $= \eta$; $k = 1$) is compared with a series of rubbers ($k = 0$) of varying shear moduli (n), a unique curve is obtained when p (percentage "bitumen softer" answers) is plotted against nt. The time required to give an equality point corresponding to the case where η is numerically equal to n, is not equal to the time-unit from which η is calculated (1 sec.) but to a fraction ($\alpha = 1/3$) of this value.[4]

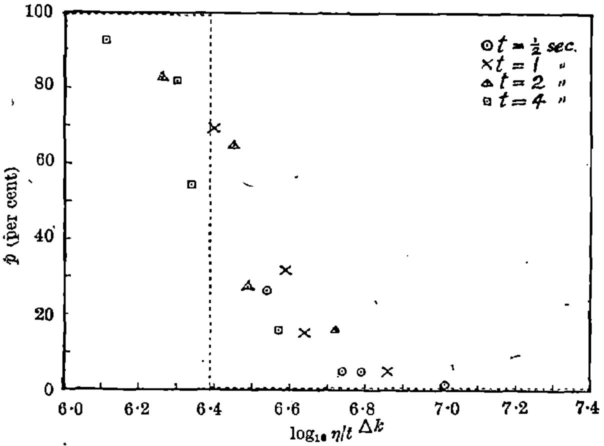

Fig. 1.

The dotted lines represent the curves obtained from the data from the compression machine.

In order to study further the relationship between α and the difference between the k-values of the materials (Δk), we have done two further experiments (I and II) with ten subjects, giving three sessions per experiment and 32 judgments per session, that is, 960 judgments per experiment. A series of fluid bitumens was compared with (I) an unvulcanized rubber ($k = 0{\cdot}50$; $\psi = 2{\cdot}5 \times 10^6$) (we are indebted to Dr. L. R. G. Treloar, of the British Rubber Producers' Research Association, for this material); and (II), a synthetic rubber-clay-Vaseline mixture ($k = 0{\cdot}22$; $\psi = 4{\cdot}0 \times 10^6$). The Δ k-values were, therefore, 0·50 and 0·78.

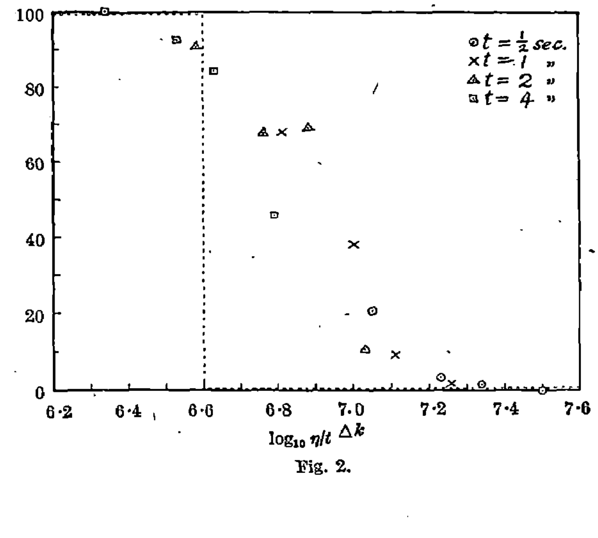

Fig. 2.

The accompanying graphs show that unique curves are obtained by plotting p against log ($\eta/t^{\Delta k}$). Thus, from subjective comparisons of the firmness of a material with that of a true fluid, we can derive the dissipation coefficient, although no conscious judgment of this property is given by the subjects. This is a strong point in favour of the use of the Nutting type of equation, especially where subjective judgments are of industrial importance.

In experiment I, α is 0·98 and in II, 0·45, subject to a fair margin of error. The relationship between α and k should be further investigated.

Hospitality in Australia for Scientific Workers

AMONG the ranks of scientific workers in Great Britain there must be a considerable number who are unable to make any direct contribution towards the nation's war effort and whose researches have been seriously interfered with or stopped by various circumstances arising from the War.

Australian men of science have widely expressed their wish to extend the hospitality of their laboratories to such scientific colleagues in Great Britain, so that they may continue with their work.

The Australian National Research Council has made inquiries to ascertain what facilities the universities and research institutes of Australia can offer, not only to colleagues in Great Britain, but also to those men of science in other parts of the Empire who normally would proceed to the United Kingdom for study leave or postgraduate courses but are now debarred from doing so.

The response to this inquiry indicates that scientific laboratories throughout Australia are anxious to offer such hospitality, and that facilities are available for workers in almost all branches of science.

In view of certain limitations of the facilities available in certain laboratories, my Council would be glad to advise any scientific colleagues who may wish to come and work in Australia as to which institutions can offer them the facilities required for their particular investigations.

RESEARCH ITEMS

Biological Productivity of Lakes

IN studying the biological productivity of lakes, quantitative determinations of the standing crop of plants (producers) and of animals (consumers) have been made on several Wisconsin lakes by C. Juday, who described his results at the Autumn Meeting of the U.S. National Academy of Sciences held during October 13–15. The ratio of plants to animals is not a static, but a dynamic, factor, which shows seasonal and annual fluctuations, as well as variations in shorter periods of time, especially with respect to the phytoplankton. The annual variations range from 10 : 1 to 15 : 1 when stated in terms of live weight. In soft-water lakes the ratio can be readily modified by the use of organic fertilizers, such as soy bean meal and cotton seed meal. The effect of these fertilizer fluctuations on the growth-rate of fishes is now being investigated. Manning and R. E. Juday (1941) found that the biological productivity of the upper stratum (epilimnion) of a lake is correlated, within certain limits, with the chlorophyll content of the phytoplankton. In terms of glucose, the computed productivity ranged from 14 to 44 kgm. per hectare a day in August in seven lakes.

Modification of Injury Produced by Röntgen Radiation

ATTEMPTS to modify the amount of injury produced by Röntgen radiation are of interest from theoretical and practical points of view. They indicate the importance of indirect effects of the radiation in the final injury to cells under certain conditions, and offer some hope of improving the tumour injury—tissue injury ratio in cancer therapy. Two types of experiments in which the radio-sensitivity of cells have been modified were described by T. C. Evans at the Autumn Meeting of the U.S. National Academy of Sciences held during October 13–15. It has been found that the effect of Röntgen radiation of decreasing the fertilizing power of Arbacia sperm is, within certain limits, proportionately increased as the concentration of the sperm in sea water (during irradiation) is decreased. The resistance of the sperm to this action of the radiation is greatly increased upon the addition of sufficient amounts of (1) dead sperm, (2) living sperm of Nereis, (3) egg albumen, (4) gelatin and (5) Arbacia egg jelly. Another line of evidence for the effect of the 'medium' on the radio-sensitivity of cells is derived from experiments on the skin of certain mammals. In these experiments it has been found that the resistance of the skin is increased when the circulation of the blood is blocked during the irradiation.

Heavy Carbon Isotope in Plant Metabolism

THE use of the heavy carbon isotope in studies of plant metabolism was discussed by R. Belkengren, A. O. Nier and G. O. Burr, of the University of Minnesota, at the Autumn Meeting of the U.S. National Academy of Sciences held during October 13–15. The normal carbon dioxide of the air contains about 1·1 per cent of the carbon isotope ^{13}C. Using methane in a thermal diffusion column, the heavy carbon was increased to 5–10 per cent. This methane was burned to carbon dioxide and fed to green plants by photosynthesis. The accuracy of the mass spectrograph is such that the percentage of heavy carbon dioxide $\left(\frac{\text{mass } 45}{\text{mass } 44} \times 100\right)$ can be found to the second decimal place. Hence the amount of heavy carbon that has gone into any chemical fraction of the plant can be determined with fair accuracy even after considerable dilution. Young bean and radish plants were used for the experiments reported. When exposed to heavy carbon dioxide in darkness, the leaves of the bean seedling do not form a measurable amount of any diffusible compound that is transported and respired in other parts of the plant. However, in light the newly formed photosynthate is rapidly transported to all parts of the plant and incorporated at varying rates into every chemical fraction thus far examined. Within three hours root tips 30 cm. from the leaf are respiring heavy carbon dioxide, and after 24 hours the terminal centimetre of growing roots contains 30 per cent of the newly fed carbon. The conversion of newly formed photosynthate into chlorophyll, xanthophyll, lipids, cellulose, starch, protein, amino acids and amides has been measured.

A Trisomic Grasshopper

H. G. CALLON (*J. Hered.*, 32, 296–298 ; 1941) has found a trisomic individual of the grasshopper *Mecostethus grossus*, which is a rare species in Britain. There is usually only one chiasma situated near the centromere in each bivalent of *M. grossus*. Consequently, a trivalent is never formed in this trisomic individual, but the three homologous chromosomes are represented by a bivalent and a univalent. This univalent may be passive in the spindle similar to the *X*-chromosome, and may be included in one telophase group or it may, unlike the *X*-chromosome, be included in the spindle and remain near the equator until after the disjunction of the bivalents. As a result of this latter process, a diploid restitution nucleus is formed. The external appearance of the trisomic individual was similar to a normal male *M. grossus*.

Heparin

THE unit of early crude preparations of heparin, the blood anti-coagulant, originally found in liver and afterwards in most tissues, was defined as the minimum quantity necessary to keep 1 ml. of cat blood fluid for 24 hours at 0°. Units so defined in terms of some potentially variable animal reaction have not the advantage of units stated to be the specific activity contained in a fixed weight of standard preparation and measurable by any quantitative and standard biological test. Workers in Toronto have already proposed the crystalline barium salt of heparin as a standard having 100 units/mgm. F. C. MacIntosh (*Biochem. J.*, **35**, 770, 776 ; 1941) has now devised a simple method of test wherein oxalated horse plasma, to which heparin has been added, is recalcified in the presence of an excess of thrombokinase. The clotting time depends on the concentration of heparin. The method reveals differences in activity which are definitely greater than those determined for the same samples by methods using whole mammalian blood, and suggests that even crystalline barium heparin contains several individuals the activity of which appears to be unequally directed towards the different stages of the coagulation process. He also describes a colorimetric method for the standardization of heparin. Any high molecular weight sulphuric-acid ester will give a characteristic colour change when added to an aqueous solution of a metachromatic dye such as toluidin blue. The effectiveness of any substance in producing this colour change appears to be roughly proportional to its anticoagulant potency as obtained by the plasma-kinase method. A number of synthetic anticoagulants have thus been compared with heparin; for example, chlorazol fast pink and Bayer 205 (Germanin) have anticoagulant activities of the same order as heparin by the biological and colour tests, although their action may not be identical with that of heparin.

The Hindu Kush Earthquake of November 21, 1939

THIS earthquake has been studied especially by S. M. Mukherjee and A. R. Pillai, of the Colaba Observatory, Bombay ("The Hindu Kush Earthquake of November 21, 1939", by S. M. Mukherjee and A. R. Pillai, India Meteorological Department, Sci. Notes, 8, No. 91, pp. 85–90 + 2 pages of reproductions of seismograms). By Geiger's method of least squares, the epicentre of the earthquake was obtained at 36° 11′ N. and 70° 53′ E. The depth of focus was found to be 210 ± 14 km., which makes the earthquake a deep-focus shock. The hypocentral time is obtained as 11h. 01m. 43s. U.T. The authors note that there is a tendency for the Hindu Kush shocks to originate from very near the same focus, and also that this earthquake was recorded with initial compression at Bombay and the European stations, similar to most of the preceding shocks from the same epicentral region. It is remarked that the Hindu Kush earthquakes of a strong nature tend to occur in winter, while the weaker ones occur at all seasons. All these facts point to the possibility that all shocks from this region may originate from the same causes and by the same mechanism. The authors recognized the pulse *sP* at about 8°, the smallest epicentral distance for which seismograms were available. It is suggested that for the Hindu Kush earthquakes, a study of the *sP* phase may afford very reliable information concerning the epicentre and depth of focus of the shocks from the seismograms of a single Indian station. The desirability of more open time-scales on the seismograms is suggested.

The Microcoulomb Experiment

UNDER this title, Prof. F. Ehrenhaft has published (*Philosophy of Science*, **8**, 3; 1941) a résumé of his work, extending over thirty years, on the charges carried by minute solid particles in gases. It is recalled that, so long ago as 1909, using a method similar to that of the well-known Millikan experiment, Ehrenhaft obtained a value $4 \cdot 6 \times 10^{-10}$ E.S.U. for the mean charge on particles of colloidal silver. Certain particles, however, gave values for the charge considerably smaller, in some cases only one tenth of the electronic charge. The present article summarizes the very extensive and protracted researches carried out by the author, first at his Institute in Vienna, and later, after his expulsion from the Institute, abroad, into the genuineness of this effect. The charges have been studied in various forms of apparatus, both at normal and at high pressures. Particles of wax and selenium of perfect sphericity as viewed under the microscope have been prepared and studied. In order to avoid the uncertainties associated with the use of Stokes's law as a means of determining the masses of these minute spheres, Ehrenhaft has worked out a microscopical technique for the direct determination of their diameters, and produces evidence that the density of the particles is identical with that of the same substance in bulk. The mass is thus determined directly, without reference to the laws of motion through a viscous medium. The very ingenious microscopic technique is fully described in the paper. Prof. Ehrenhaft believes that the anomalous effects are genuine, and that in many cases the particles studied carry charges which differ from the fundamental electronic charge, or integral multiples of this charge, by amounts well beyond the limits of experimental error.

Sodium Arsenites

THE composition of the alkali arsenites is not very well established, in spite of the fact that very large quantities of sodium arsenite have been used in the past few years for the control of harmful insects; more than 7¼ million pounds were used in the United States in 1938–40 for three kinds of insects alone. O. A. Nelson (*J. Amer. Chem. Soc.*, 63, 1870; 1941) has made a phase rule analysis of the system containing Na_2O, As_2O_3 and H_2O, and the results show that solid phases of the following compositions separate: (1) Na_2O, $3As_2O_3$, (2) Na_2O, As_2O_3, (3) $2Na_2O$, As_2O_3, $7H_2O$ and (4) $2Na_2O$, As_2O_3. Of these, (1) and (3) were not previously known. The system was examined by Schreinemakers and De Baat in 1917 and some of their results could not be confirmed by Nelson, who gives reasons for supposing that these results are improbable.

XZ Aurigæ: An *N*-Type Variable

G. Alter and D. L. Edwards have issued a paper with this title (*Mon. Not. Roy. Astro. Soc.*, **101**, 5; 1941), which shows that this star is not a β-Lyræ type as recorded by Prager and Schneller. This discovery was made by an accidental comparison of a photovisual plate of a star field with the corresponding Franklin-Adams chart, when it was found that XZ Aurigæ was not present on the chart (limiting mag. 15), while it appeared on the Sidmouth photovisual plate as a star of magnitude 10. Further exposures showed that the star had a colour index of about $+4^m$, for which reason it was necessary to make fairly long exposure-times for photographic magnitudes to obtain a star image with the Mond Astrograph. Thirty-four comparison stars were chosen in the surrounding region, their magnitude range being large enough to exceed that of XZ Aurigæ in the photovisual scale, though not sufficiently large to secure the extension of the fainter photographic magnitudes, as the available apertures are too small. On three occasions only was it possible to secure both photographic and photovisual magnitudes, and the colour index was found to be $+3 \cdot 8$ to $+5 \cdot 0$. In view of this large colour index the 12-inch McClean objective prism was used to obtain the spectrum, but good photographs could not be taken owing to poor weather conditions and also to the fact that the star was close to the limiting magnitude obtainable with the instrument. The best photograph taken on March 30, although of poor definition, showed that the spectrum is almost certainly of late *N*-type—a view supported by the large colour index obtained. Wolf's observations, which were published in 1917, showed that the photographic magnitude was 14·5, and this is corroborated by the present investigation. It is remarkable that the colour index was found to change by about one magnitude in 10 days.

ASPECTS OF MODERN GEOLOGY

By PROF. EDSON S. BASTIN

University of Chicago

FOUR notable geological symposia were held on September 25 and 26 during the celebration of the fiftieth anniversary of the University of Chicago and with the co-operation of the Geological Society of America and the American Association for the Advancement of Science. All four symposia dealt with the frontiers of geological research.

The climax of the geological programme was undoubtedly the address of Reginald A. Daly, of Harvard University, on glaciation and submarine valleys. This was a remarkably lucid exposition of his hypothesis of the origin of submarine valleys by silty bottom currents or underflows operating under the general control of Pleistocene glaciation and its attendant effects on sea-levels.

Clay Materials

The first symposium, on the structure, properties and occurrence of clay materials and their practical application, was opened by Dr. Ralph E. Grim, of the Illinois Geological Survey, long a leader in clay research. Dr. Grim reviewed the old ideas of the composition of clay materials and the researches of the past fifteen years using modern research tools, that have led to the present generally accepted concept that clays are composed essentially of minute crystalline particles of one or more members of a few groups known as the clay minerals. The composition, structure and properties of these components were discussed and some new interpretations suggested.

Following this paper Dr. Sterling B. Hendricks, of the U.S. Bureau of Plant Industry, described in detail the lattice structure of many of the clay minerals.

Prof. W. P. Kelley, of the College of Agriculture of the University of California, discriminatingly reviewed the importance of clay researches to modern agriculture and emphasized the close relationship between soil science and geology.

Prof. F. H. Norton, of the Massachusetts Institute of Technology, pointed out that in addition to the clay minerals there are various mineral impurities, and that clays also contain soluble salts from the ground water which have a strong influence on their physical properties. Clay, having such a large surface, is very sensitive to adsorbed ions, and many of the variations observed in clays are traceable to this adsorbed material.

The symposium concluded with a discussion by Dr. Hans F. Winterkorn, of the College of Engineering, University of Missouri, of the importance of clay research in engineering construction, particularly of highways and dams, and the use of base-exchange and other methods for stabilizing such constructions.

Coals

The second symposium dealt with the physical constitution of coals and their practical significance and was under the leadership of Dr. Gilbert H. Cady, long in charge of the important coal studies of the Illinois Geological Survey. Dr. Cady pointed out that a satisfactory classification of coals into types must rest upon an understanding of the physical and chemical properties of the primary components of coal—vitrain, clarain, durain and fusain. Increased knowledge of these components has led to the important practical result that it is now possible to synthesize coals or modify them to conform to petrographical specifications.

Dr. H. H. Lowry, of the Carnegie Institute of Technology, reviewed the data on the chemical nature of the banded constituents of coals and emphasized the fact that essentially distinct types of chemical compounds peculiar to each of the banded components have not been found. Recent progress in Britain in the study of coals was reviewed by Prof. C. E. Marshall, of the University of Birmingham, who further emphasized the increasing importance of microscopic study of both the plant and the mineral components of coals to efficient utilization. That in the United States improved marketing and utilization practice based upon the newer knowledge of coal constituents is well under way was emphasized by Capt. Louis C. McCabe, of the U.S. Quartermaster Corps. In the coking of coals and in hydrogenization, knowledge of the coal components are also of great import as emphasized by George C. Sprunk, of the U.S. Bureau of Mines, who pointed out, for example, that the portions of coal that are translucent under the microscope are readily hydrogenized and give high yields of liquid fuels, whereas components that are opaque are difficult to liquefy.

The influence of metamorphism on the coal constituents was stressed by Dr. C. E. Dapples, of Northwestern University, who pointed out that some constituents such as cannel and durain tend to resist physical change, whereas fusain, clarain, vitrain and resinous bodies alter their physical properties with increase in rank.

Glacial Geology

The third symposium was concerned with the newer developments in the field of glacial geology, principally in North America, and was opened by Prof. Richard F. Flint, of Yale University. Several problems of very fundamental importance were discussed by him, one of these being the cause of the locations of the great ice caps. It has long been held that these ice caps grew *in situ*, but that hypothesis seems to encounter insuperable meteorological difficulties. It was pointed out that each central area of ice accumulation stands in definite relation to a high range of mountains—the Torngat Range of Labrador, the great mountains of Baffin Island, and the Swedish-Norwegian mountains, respectively. It seems likely that it was on these mountains that the snow fell, forming Alpine glaciers, and that these glaciers coalesced, growing outward away from the mountains and thickening to such an extent that they became high enough and cold enough to catch snowfall themselves, thereby shifting the locus of maximum snowfall away from the mountains, and eventually allowing the ice caps to bury the mountains.

Space does not permit the mentioning of all the contributions to this symposium, but the northern extent of glaciation in North America is certainly a matter of very general interest, and according to Dr. A. L. Washburn, of Yale University, this is still an unsolved problem the solution of which is handicapped by the fact that sea ice may produce some features which simulate the work of glacier ice. Recent field investigation indicates that Victoria Island, with an area of about 79,000 square miles, and the very much smaller Royal Geographical

Society Islands, were definitely glaciated during the Ice Age, and that glaciation of at least the southern portion of Banks Island is probable. Evidence obtained by a Canadian Government Expedition in 1908–9 suggests glaciation of Melville Island. No geological evidence seems to be on record indicating lack of glaciation on other islands in region. It appears that glaciation was derable areal importance in Canada's ctic, but informa- tion concerning areal extent must await fur Dr. D. A. Nichols, of the of Geology and Topography, that esent knowledge of the glacial geology has been gleaned incidentally to studies ler aspects of geology, notably the economic, and that great opportunities for specialized glacial studies exist. Correlation of glacial and marine features of the Atlantic Coast was considered by Prof. Paul MacClintock, of Princeton University, and the contributions of botanical studies to knowledge of post-glacial climates were presented by Prof. W. S. Cooper, of the University of Minnesota, who concluded that the record from pollen studies and the facts of plant geography apparently agree in indicating a mid-post-Pleistocene warm-dry period followed by a return towards cool-moist conditions during the last few thousand years.

Petroleum

The fourth symposium related to geological frontiers in the search for oil and was opened by A. I. Levorsen, chairman of the Research Committee of the American Association of Petroleum Geologists. Among the many interesting points brought out by Mr. Levorsen in his discussion of trends in petroleum geology was a point often overlooked by those interested in mineral resources, namely, that petroleum reserves contrast with reserves of other mineral resources in that it is impossible to estimate them in advance of discovery by drilling. Thus, whatever may be the *true* reserves, *estimated* reserves have always been small, and continued discovery is essential to continued development.

The role of modern surface methods in the search for oil was described by E. W. Owen, president of the American Association of Petroleum Geologists, and the role of micro-palæontology by Prof. Carey Croneis, of the University of Chicago. Dr. W. C. Krumbein, also of the University of Chicago, spoke of the importance of a fuller knowledge of the principles of sedimentation in the search for stratigraphic oil traps in contrast to structural traps.

In speaking of the role of ground water in petroleum accumulation, Prof. F. B. Plummer, of the University of Texas, concluded that recent extensive investigations of pore sizes, of the forces required to move liquid and gas hydrocarbons through them, of the variation in subsurface pressures, and of the forces due to interfacial tension, indicate that crude oil droplets cannot move through a porous sand from synclinal positions to anticlinal positions by gravity alone. The conclusion is reached that hydrocarbons migrate largely as gas particles and partly as liquid films enveloping gas bubbles, along with the slow downward movement of the ground water towards the lower part of the region, and that as the tiny gas bubbles come within the influence of decidedly low pressures they accumulate in the trap.

FOOD INVESTIGATIONS IN CANADA

FOOD studies constitute a very important field of research. In the National Research Laboratories at Ottawa nearly one half of the work in the Division of Biology and Agriculture now relates to food. Preparation, processing, packaging and preservation during transport are all subjects of research.

Since the autumn of 1939 the investigations in the food laboratories of the National Research Council have been directed almost wholly to new problems arising from the War. Among these is improved preservation of perishable products such as bacon and eggs shipped to Great Britain, the object being to overcome the effects of the longer shipping period and the lack of refrigerated space. The utilization of market poultry and other perishable products for which the export market has been reduced, and improvements in the nutritional value of canned goods and other processed foods have been studied. Special problems such as the storage of blood for transfusion, which the storage laboratories are well equipped to study, have also been given attention.

Poultry

One of the first problems undertaken in the food storage laboratories dealt with the preservation of dressed poultry in the frozen state. The results of this study led to definite recommendations as to pre-cooling, freezing, packaging and storage practices that should be followed to avoid impairment in appearance or eating quality. A new package was designed to facilitate moisture-proof sealing of the product in order to prevent deterioration from surface-drying during storage.

The use of the improved package for dressed poultry for export has been restricted owing to the shortage of refrigerated space on ocean-going vessels. This emphasized the importance of canning. A canning laboratory was established towards the end of 1939 and has now been almost completely equipped.

Following a preliminary survey of the canned poultry on the domestic market, improved methods of processing have been developed and their suitability to plant conditions demonstrated. The recommended processes include pressure pre-cooking, retort pre-cooking, improved methods of handling the raw and finished product and broth, and the use of side-opening cans, lacquered with a gold storing-type enamel which adds to the attractiveness without materially affecting the total cost. Attention has also been given to the development of a grading system, and apparatus has been devised for quantitative separation of the meat and jelly and for measuring the strength of the meat broth and jelly.

Another set of experiments was concerned with the development of rancidity in poultry fat during storage. Prompt pre-cooling and freezing were found essential to the preservation of quality.

Eggs

Eggs shipped to Great Britain in ordinary storage are subject to deterioration from the growth of micro-organisms on the exterior or interior of the eggs, desiccation through loss of moisture, and thinning of the 'thick' white through loss of carbon dioxide. Preservative treatments have been tested and methods of handling investigated. Oil dipping appears to be the most practicable commercial treatment. Canadian spray-dried whole eggs have been examined for export to Great Britain.

Pork

The frozen storage of pork is of considerable importance since the seasonal production of pigs in Canada demands that a considerable amount of pork must be placed in storage during peak seasons in order to maintain reasonably uniform export of bacon throughout the year. Studies have been made on colour changes and on development of rancidity in pork during storage.

Bacon

Investigations into the curing and transport of Wiltshire bacon, begun in 1938, have been continued as the major project in the food laboratories of the National Research Council. Before the War this work was extended to include comparative tests of Canadian and Danish bacon as received in Great Britain.

Wiltshire bacon is the most important perishable product which Canada exports to Great Britain during peace or war. Bacon studies undertaken before the War included a survey of the curing processes used in Canada. This disclosed variations in the method of producing Wiltshire sides in different plants. An extensive study of the bacon produced by these factories followed. The companies concerned co-operated actively with the National Research Council in these studies.

The results showed that the principal variation in Canadian bacon with respect to bacteriological, chemical and physical composition and such attributes of quality as colour, colour stability and tenderness was in the product manufactured in different factories. This indicated that differences in the curing process, rather than the differential response of individual carcasses to curing, were the primary cause of variable quality. The market value, of course, is also affected by the preference of consumers for sides of a certain conformation.

In recent months more emphasis has been laid on methods for converting the extremely perishable unsmoked bacon normally shipped to England into a form that will withstand the delays in transport while maintaining the highest possible quality. It has been found that smoked bacon is less perishable than the unsmoked material. The possibility of smoking the product in Canada, and the use of cures that render the product less perishable are being investigated.

Smoking is almost universally used in the processing of bacon but Canadian Wiltshire sides have hitherto been exported to Great Britain in the 'green' or unsmoked condition and smoked there. It is generally accepted that smoking has a preservative action but little information of a quantitative nature is available. Extensive studies have therefore been undertaken on the relative perishability of smoked and unsmoked bacon as judged by colour measurement, peroxide oxygen content of fat, and surface bacterial counts. In the storage studies unsmoked bacon was found to be rancid after forty-two days, whereas the smoked product was usually satisfactory after seventy days.

Wiltshire bacon is usually matured for two or three weeks before smoking and then consumed immediately. This procedure is believed to produce the most desirable flavour. If smoking were employed as a method of preservation during transit, the material would have to be smoked shortly after cure and then be carried through a relatively extended transport period before reaching the consumer.

As regards the research on Wiltshire bacon, it may be noted that twenty-three papers on this subject have been published in the *Canadian Journal of Research*. These papers have dealt with such subjects as: a survey of Canadian plant and curing processes; distribution of chloride; effect of heat treatment on nitrite co[illegible] colour and toughness; measurement of the colour [illegible] seasonal variations in colour; bacteriological and [illegible] during cure; the effect of temperature [illegible] nitrite content, etc. Further work [illegible] to be curtailed in favour of work [illegible] of methods of preservation of bacon [illegible] Great Britain.

Influence of Conditioning Factors

Precise control of temperature, humidity and other factors are frequently necessary for the storage and freezing of foodstuffs. Earlier investigations into the humidification and the reduction of temperature variations in cold stores have been continued. Apparatus has been developed for the measurement and control of humidity in cold stores.

Blood Storage

Shortly after the outbreak of war, certain problems relating to storage of whole blood were referred to the Division of Biology and Agriculture by the Sub-committee on Blood Storage of the Associate Committee on Medical Research. The object of these studies was to determine the conditions under which human blood could be stored for the longest possible period. This work has been completed.

Vitamin Fortification

Current attempts to raise the nutritional level of the population, including the vitamin-fortification of certain foods, have emphasized the need for information on the effect of processing and storage treatments on the vitamins, several of which are destroyed by exposure to air or by high temperature. Methods and equipment for studying these problems by chemical means are being developed.

The vitamin B complex contains at least two components that can be determined chemically by means of a fluorimeter. Such an instrument has been designed and constructed. It is cheap, simple, self-contained, stable in operation and is capable of measuring thiochrome (produced from thiamin or vitamin B_1) in concentrations as low as one part per hundred million.

Many other investigations relating to foods are under way in the laboratories of the National Research Council or in other laboratories under the programme of work decided upon by the Canadian Committee on Storage and Transport of Food.

Special mention may be made of the development and testing of improved methods of controlling temperature in refrigerated cars. In this work the Division of Physics and Electrical Engineering co-operated by designing the necessary apparatus, and the Fisheries Research Board successfully carried out test shipments of frozen fish from Prince Rupert to Montreal.

Detailed accounts of investigations in food storage and transport are contained in papers published in the *Canadian Journal of Research* and in the annual review of activities issued by the National Research Council of Canada.

RESPIRATION AND THE ASSIMILATION OF CARBON DIOXIDE

AN account of work by C. H. Werkman, L. O. Krampitz and R. G. Wood of Iowa State College on the assimilation of carbon dioxide during respiration was given on October 13 during the Autumn Meeting of the U.S. National Academy of Sciences.

The concept of heterotrophic assimilation of carbon dioxide was first established in 1935 by Wood and Werkman, while investigating the dissimilation of glycerol with the propionic acid bacteria. They observed the molar correlation between carbon dioxide disappearance and succinic acid formation and proposed the reaction: pyruvate + CO_2 → oxaloacetate, to account for this fixation of carbon dioxide. The latter four-carbon dicarboxylic acid serves as the oxidizing agent for the glycerol, resulting in the formation of succinic acid.

The concept of carbon dioxide assimilation has recently been applied to many other heterotrophic forms, including the liver tissue of mammals. It is in this tissue that the role of carbon dioxide fixation has been shown to be of fundamental importance with regard to respiration. Oxaloacetate is the cardinal compound in the main respiratory mechanism of the tissue. Consequently elucidation of the mechanism of its formation is of fundamental importance. Direct evidence for the fixation reaction has been obtained with a bacterial enzyme preparation from *M. lysodeikticus*, which is capable of bringing about the decarboxylation of oxaloacetate, that is, the reverse of fixation reaction. Thus far attempts to carboxylate pyruvate have failed. This may be due to an unfavourable equilibrium, that is, the breakdown of oxaloacetate is greatly favoured. On the other hand, pyruvate as such may not be the compound with which carbon dioxide unites but rather a derivation of pyruvate. With ^{13}C as a tracer it was possible, however, to demonstrate the fixation reaction using oxaloacetate. Decarboxylation of oxaloacetate was carried out in the presence of the enzyme and $NaHCO_3$ with an enriched ^{13}C content. The reaction was allowed to continue until the original oxaloacetate concentration was halved. The residual carbon dioxide was removed and the remaining oxaloacetate was decarboxylated to pyruvate and carbon dioxide and the latter thus obtained determined for ^{13}C. The concentration of ^{13}C was substantially above normal.

The criticism that a chemical exchange of carbon dioxide with carboxyl group, analogous to the exchange of deuterium with ionizable hydrogen, may take place was investigated. Oxaloacetate spontaneously decarboxylates slowly. An experiment similar to the above one was performed omitting the enzyme, and the residual oxaloacetate decarboxylated. The ^{13}C content of this carbon dioxide was normal.

The possibility of the enzymatic exchange of carbon dioxide with carboxyl groups of other keto acids was investigated, with an enzyme capable of oxidizing pyruvate to acetate and carbon dioxide. An experiment was conducted in which the oxidation was permitted until one half of the pyruvate remained. The residual pyruvate was decarboxylated and the ^{13}C content of the carbon dioxide was found normal. Similarly, the oxidation of α-keto glutarate to succinate was carried out, and likewise the normal ^{13}C content of carbon dioxide obtained.

Thus it has been demonstrated that the exchange reaction is specific for oxaloacetate, and apparently does not occur in other keto acids. The exchange reaction in oxaloacetate is essentially 3- and 1-carbon addition or a fixation reaction.

GAME PRESERVATION IN BURMA

THE annual report on game preservation in Burma for the year ending March 31, 1940 (Rangoon, Supt. Govt. Printing, Burma, 1941) shows that this matter is treated in Burma with the serious spirit it demands. The present policy aims at providing a sufficient number of sanctuaries to ensure that no species of Burman bird or animal becomes extinct. The following list of sanctuaries will indicate how this laudable effort is carried out under the able game warden, a member of the Burma Forest Service. It is a pity that India as a whole and the British Colonies have not made similar attempts at game preservation. There are seven sanctuaries situated in North and South Burma: Pidaung (Myitkyina), 278 sq. miles; Shwe-u-daung (E. Katha), 81 sq. miles, with another 45 sq. miles situated in the neighbouring Federated Shan States; Maymyo (summer headquarters of Government of Burma), 49 sq. miles; Moscos Islands (Tavoy), 19 sq. miles; Kahilu (Thatôn), 62 sq. miles; Mulayit (Thaungyin), 53 sq. miles; Wetthigan (Minbu), 1¾ sq. miles.

The Pidaung sanctuary is primarily constituted to protect elephants, bison, saing, sambhur, hog deer, pig, tiger, leopard, bear, pea-fowl, pheasant, jungle fowl, partridge and quail. Of these it is reported that elephant, bison and saing continue to increase, though elephants only spend part of their time in the sanctuary. On the other hand, there is a marked reduction in sambhur and hog deer found in the open plains; this is attributed to tigers and wild dogs. Four tigers are to be shot by the keepers of the sanctuary and as many wild dogs as possible, as also crows which are a serious pest to bird life in the sanctuary. Those acquainted with big-game shooting in India must have noted at times the results of the wild dog pest—whole jungles deserted by game once the animals are aware of the advent of parties of wild dogs.

The Shwe-u-daung sanctuary contains the above mentioned fauna, with the addition of *Rhinoceros sumatrensis* and the serow. There is reason to believe, says the warden, that the small band of Sumatran rhinoceros living in this sanctuary has become well established, and the evergreen hill forests covering the upper slopes of the sanctuary provide an undisturbed area where these animals can live in peace. The increase in wild dogs is giving trouble here. In the Kahilu sanctuary the animals are *Rhinoceros sumatrensis*, serow, sambhur, barking deer, mouse deer, hog deer and jungle fowl. It has been proved that the rhinoceros in this sanctuary is *R. sumatrensis* and not *R. sondaicus*, as identified some years ago from skulls by the Bombay Natural History Society. The Sumatran rhinoceros is an extremely rare animal in Burma.

Of the other sanctuaries the Maymyo contains barking deer, jungle fowl, partridge and pea-fowl; Moscos Islands, sambhur, barking deer and pig; Mulayit, barking deer, pig, tiger, and leopard; and the latest made sanctuary, the Wetthigan, which includes the lake of that name for the preservation of numerous indigenous and migratory waterfowl, of which thirty-three resident species and thirty-one migratory species have been identified.

It is of interest to hear that the reservation of other sanctuaries is under consideration. The only cause for alarm is the warden's statement that "there is at present no co-ordination between the civil authorities who are responsible for the issue of fire-arms and ammunition, and the Forest Department which is mainly responsible for the protection of wild animals and birds". It is to be hoped that this defect in a far-sighted policy may be removed.

IRISH FISHERIES

THE quantity of sea fish landed in Eire during 1939 was larger than that landed in any year since 1931, and its value reached the highest figure since 1929 (Department of Agriculture (Fisheries Branch). Report on the Sea and Inland Fisheries for the Year 1939. Dublin, Published by the Stationery Office). The increased landings in 1939 were due to heavier catches of demersal fish by the stream trawlers operating from Dublin, and of mackerel by inshore fishermen on the County of Kerry coast-line. The total catch of whiting in 1939 seems to be the highest recorded for the country, and landings of prime fish, cod and hake, were the heaviest for several years. The quantitative yield of the herring fisheries was less in 1939 than in 1938, but its total value was greater by £5,000. The decrease in quantity was due to the failure of the summer fishery of the north-west coast. The substantial increase in the mackerel landings was due to heavier catches in the autumn mackerel fishing off the south-west coast.

The S.S. *Muirchu* took part during the year in scientific cruises off the north and south-west coasts of Ireland. The cruise off the south-west coast was undertaken in April 1939 for the purpose of continuing the mackerel investigations begun in 1938 in collaboration with the English and French research vessels. As in the previous year mackerel eggs were found in large numbers in an area thirty to seventy miles south to south-south-west of the Fastnet Light. Hydrographic and plankton observations were the main purposes of the cruise off the north coast.

In the inland fisheries the salmon fisheries in 1939 improved but slightly in quantity compared with the years 1937 and 1938, both of which were bad years also for other countries in Western Europe. There was a lack of small and large spring fish such as have spent two or three years respectively in the sea. This was partly compensated for in some parts of the country and particularly in the west by a very good run of grilse.

Artificial propagation of salmon and trout continues; but owing to weather conditions the quantity of ova available was below normal. At the brown trout hatchery at Lough Owel, in spite of weather, there was a record output of 560,000, some of which were returned to the Lough in the fry stage and others distributed among other stations throughout the country.

Scientific investigations into the age and growth of salmon and other salmon researches are in progress. Seventeen appendixes, mainly statistical, are included in the report.

FORTHCOMING EVENTS

Saturday, January 3

JOINT MEETING OF TECHNICAL INSTITUTIONS arranged at the request of the Mines Department (in the H. H. Wills Laboratory, Royal Fort, Bristol), at 2.30 p.m.—Discussion on the Best Ways and Means of Improving the Efficient Use of Fuel and Power in Existing Industrial Plants, under Present Conditions, and to Invite Constructive Suggestions. (To be opened by Mr. J. G. Bennett.)

Monday, January 5

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m. —Dr. C. A. Freak: "Insecticides".

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 3 p.m.—Mr. Patrick FitzGerald: "The Lake Basin of Tali, Yunnan".

Thursday, January 8

TOWN AND COUNTRY PLANNING ASSOCIATION (in the Dome Lounge, Dickins and Jones, 224 Regent Street, London, W.1), at 1.20 p.m.—Mr. George Hicks, M.P.: "The Part of the Ministry of Works in Post-War Reconstruction".

Saturday, January 10

BRITISH INSTITUTION OF RADIO ENGINEERS (at the Federation of British Industries, 21 Tothill Street, London, S.W.1). Dr. W. Wilson: "Recent Developments in the Design and Application of the Cathode Ray Oscillograph".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

EDUCATIONAL PSYCHOLOGIST in connexion with the Child Guidance Clinic—The Director of Education, Education Offices, 15 John Street, Sunderland (January 9).

LIBRARIAN (WOMAN)—The Principal's Secretary, Royal Holloway College, Englefield Green, Surrey (January 10).

ELECTRICAL ENGINEER under the Engineer-in-Chief—The Secretary, Tyne Improvement Commission, Newcastle-upon-Tyne 1 (endorsed 'Electrical Engineer') (January 12).

RESEARCH ASSISTANT TO UNDERTAKE WORK ON HOT-TINNING—The Secretary, Tin Research Institute, Fraser Road, Greenford, Middlesex (January 17).

HEAD OF THE PHYSICS DEPARTMENT—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (January 17).

EDUCATIONAL PSYCHOLOGIST, a MEDICAL DIRECTOR and PSYCHIATRIST, and a PSYCHIATRIC SOCIAL WORKER, in connexion with a Child Guidance Clinic—The Director of Education, Municipal Building, Preston (January 17).

GARDINER CHAIR OF CHEMISTRY—The Acting Secretary, University Court, The University, Glasgow (February 8).

BACKGROUND TO NATIONAL PLANNING

THE need for reconstruction, using the word in its largest sense, is world wide. Nevertheless, it must be realized that in many ways, as Mr. Anthony Eden implied in his broadcast talk on January 4 dealing with his recent visit to the U.S.S.R., the internal affairs of any country are peculiar to that country. Schemes of reconstructions suitable for one country might therefore not be appropriate elsewhere. Here it is proposed to consider recent literature dealing with the subject in Great Britain.

The summary report recently issued of the Oxford Conference of the Town and Country Planning Association* held last spring emphasizes, if that were needed, that the value of the Conference would emerge over a period, rather than in tangible results registered during the week-end. The volume makes available for the first time a clear and comprehensive account of the six sessions and relates them to the main aim of the Conference, namely, to crystallize and carry a stage further the national planning policy outlined in the nine agreed points of the Report of the Royal Commission on the Distribution of the Industrial Population. In doing so it provides an admirable yardstick by which progress can be measured, and in this respect can well be compared with Gilbert and Elizabeth McAllister's "Town and Country Planning" (see NATURE, Sept. 27, p. 353).

The need for such a background in considering the approach to post-war reconstruction, as well as for something of a yardstick for assessing progress, tends to grow rather than diminish. Such a measuring rod is essential in maintaining a sense of perspective in the growing literature of pamphlets, many of which are wholly admirable, and of the reports and studies of special aspects of the subject which are now appearing. It is also invaluable in assessing the actual proposals which may be formulated by the Government in the Bill to implement some of the findings of the Uthwatt Committee, and by local or professional authorities or institutions. The background provided by volumes of the type of the report of the Town and Country Planning Association is essential for the development of the principles by which the new pattern must be constructed and individual contributions assessed.

One of the happiest efforts to provide such a background has been Mr. F. J. Osborn's "Overture to Planning" in the Rebuilding Britain Series†, in which he emphasizes the need for clarifying standards of planning before they can be applied by a central department, as well as the necessity for founding planning firmly in the permanent needs of humanity. Towns must be shaped to answer to the needs of the family and industry and of the social life which enfolds them. Accordingly, it is imperative that there should be a clear idea of the new social pattern in which reconstruction will take place and of the several planes of social organization—the individual, the family, the local community, the region, the nation, and the commonwealth or family of nations.

---

* Replanning Britain : Being a Summarized Report of the Oxford Conference of the Town and Country Planning Association, Spring 1941. Edited by F. E. Towndrow. Pp. 173. (London : Faber and Faber, Ltd., 1941.) 7*s*. 6*d*. net.

† Overture to Planning. By F. J. Osborn. (Rebuilding Britain Series, No. 1.) Pp. 29. (London : Faber and Faber, Ltd., 1941.) 1*s*. net.

The broadsheet "The New Pattern" in which such ideas are developed is one of the many valuable contributions which Planning (P E P) has made to the problem of re-integration and to planning for reconstruction which really meets contemporary needs and in which the several parts form a harmonious whole. In a more limited sphere the same conception inspires a pamphlet "Britain Must Rebuild" in the Democratic Order Series by Mr. Frank Pick*, whose death will be a great loss to Great Britain. While nothing short of regional planning offers the opportunity for a stable settlement, even deeper than the need for new demographic survey is that for an understanding of the social unit upon which democracy is to be built. That unit must involve all classes and carry within it no class distinction. Mr. Pick believed in the need for a correct and natural conception of the social unit, without which the social structure cannot be secure, and he emphasized the distinction between town and country. There must be a radical break between town and country; neither can be fittingly or properly built up until the social unit is defined.

This stress on the place of agriculture in planning policy—the insistence that as a first step no land may on any account be taken out of agriculture, and no land suitable for agriculture may be used for any other purpose—is a reminder that the necessity for planning agriculture for food supply makes some concrete measure of reconstruction and planning in the relations of town and country essential. Without at least the negative approach of resolute prohibition, neither utility nor amenity will be served in country or in town.

It would be unfair to characterize Mr. Pick's pamphlet as negative, but it is full of warnings as to the dangers which attend a policy of neglect or drift. A definite change in the national attitude must at some moment be realized, and the introduction of the expected Reconstruction Bill may well be the moment. Beyond the details of compensation and betterment, the interests of the people must override the interests of the owners, and a sharp, firm line must be drawn and maintained; the needs of agriculture, amenities and recreation must be provided for before we turn to planning and the location of industry, as "Replanning Britain" abundantly makes plain.

In regard to industry, Mr. Pick insists on the concentration and not the dispersal of industry, taking the trading estate as the model. He advocates compact housing and a new approach to regulation which eliminates fixed by-laws but visits severe penalties on the builder who tries to slip through them. The basis of any plan for rebuilding Britain is transport, and here again Mr. Pick concentrates attention on the function and purpose which the road or street is to serve, and on designing it to that end, subservient to the plan or scheme for the region. He visualizes the railway station as a nuclear point and stresses the conception of the city as a social organism, the vital organs of which should be aptly placed and proportional to the work they have to do. The awkward problem of blending town and country is met by a device of wedges of park and wood tapering inward and of houses and buildings tapering outwards around the central core.

In the planning of cities and towns, site control, sentimental fondness for the old, and the lack of an architectural style are still the three major difficulties. In regard to the first, the recommendations of the Uthwatt Committee have already indicated the line of advance. The second difficulty is being shattered by enemy bombardment as well as by the general disturbance of civil life caused by evacuation, dispersal of industries and the like. The third difficulty is one primarily for the architect through his professional associations, though not for him alone. The clients as well as the architects need education and imaginative insight if we are to develop a living architecture which finds expression in appropriate cultural forms in all the new and old materials which now are to our hand.

Mr. Pick had very clear ideas on the danger inherent in functional building, on the importance of planning the countryside, including its buildings, as country, the treatment of farms and the necessity of clearing away the ruins of decayed industry as well as of avoiding either sectional settlement of building or the tyranny of the expert or bureaucrat. He gives us a vision of the possibilities once we have chosen a pattern and address ourselves resolutely to the co-operative task of achieving it; and his concluding suggestion regarding the classification and labelling of buildings according to their fitness and suitability, if not of architectural merit, might well supply a practical incentive at little cost to better planning and building.

---

* Britain Must Rebuild: a Pattern for Planning. By Frank Pick. (The Democratic Order, No. 17.) Pp. 64. (London: Kegan Paul and Co., Ltd., 1941.) 1s. net.

The work of educating public opinion and clarifying the issues is clearly proceeding apace, and on the whole it is probably true that in this, as in some other fields, such as production, opinion is ripe for much more drastic and resolute action than the Government has yet proposed. Moreover, not merely are the principles and background of planning being vigorously explored, but also much of the detailed investigation incidental to the framing or execution of any reconstruction plans is being actively pursued. Already three interim reports have appeared from the Reconstruction Committees of the Royal Institute of British Architects, and a recent report of the Association of Architects, Surveyors and Technical Assistants makes a further contribution in this field.

The first of the reports of the Royal Institute of British Architects deals with planning and amenities, and reiterates the arguments in favour of a national planning authority. For post-war operation, any plan must be mainly constructive rather than restrictive in character, and for this reason the present exemptions from planning are undesirable. As the recent P E P broadsheet on "Publicly Owned Land" indicates, although the Forestry Commissioners, the Duchy of Lancaster, and the Commissioners of Crown Lands are not subject to the existing planning Acts, in practice they consult or co-operate with local planning authorities. Nevertheless there is much to be said for bringing the Crown lands and all other State-owned lands within the purview of the planning Acts in the normal way.

The interim report of the Royal Institute of British Architects indicates the machinery essential for a national plan, and the matters with which experts responsible for the preparation of such a plan must be concerned. The national authority should include the Ordnance Survey, at present under the Ministry of Agriculture; the value of a new map on a scale of about three inches to the mile for the purpose of a national plan, fully contoured, is stressed. The authority should include the present planning department of the Ministry of Health, but not the detailed work of housing, the trunk roads and new roads, at present dealt with by the Ministry of Transport, as well as railways, ports, canals and public utilities, essential agricultural reservations, national and regional open spaces, approval and reservation of aerodrome sites. It should be supported by regional offices to deal promptly with these matters on lines laid down by the central authority as well as by regional groupings of the local authorities, which will decide as to suitable local planning areas and any necessary financial adjustments.

This outline alone indicates how important a contribution the establishment now of a national planning authority might well make not merely to post-war reconstruction but also to the co-ordination of our war effort.

This is equally true of the proposals, in the second interim report, on war-time housing, and in the report issued by the Association of Architects, Surveyors and Technical Assistants. Both these reports emphasize the way in which present and post-war needs are related and the importance of greater co-ordination among the authorities responsible for war-time housing. The report of the Royal Institute of British Architects recommends that in new *war-time* housing the single-family *peace-time* standard house should be abandoned in favour of hostel dwellings providing minimum living and sleeping accommodation with communal facilities for feeding, heating, washing and relaxation. The choice between permanent and temporary types of building should be governed by long-term as well as by immediate considerations. Of the permanent types, two- or three-storied structures should be built with the maximum amount of standardization, and this accommodation should be designed so as to provide for conversion later to peace-time housing standards.

The same conception of new housing of a permanent nature designed to give a high degree of protection, standardized to ensure speed of erection and utilize unskilled labour and capable of being adapted later as family homes and post-war housing is found in the Association of Architects, Surveyors and Technical Assistants' report, "Why Wait for the Blitz ?". Much of this report is concerned with provision of rest centres and feeding-centres in and outside the towns, and with the administrative work required, including the establishment of regional councils representing local authorities, trades' councils and Government departments, with full powers to execute schemes and to organize pools of labour and materials on a regional basis. It also includes a description of the blast- and splinter-proof housing devised by Mr. O. N. Arup in the scheme prepared for Clydeside to illustrate how it can be converted to a peace-time housing design.

The advantage of designing new war-time buildings to serve post-war needs in this way is obvious, but it may be lost entirely unless such construction is planned in harmony with long-term national and not merely sectional needs. Similar considerations give urgency to the recommendations in the Royal Institute of British Architects' first report regarding the control of design and the immediate investigation of the possibilities in the distribution of hot water and heat on an area basis, the saving of waste and salvage of useful material, the utilization of spoil heaps, disposal of refuse matter on a mechanical basis and the avoidance of atmospheric pollution. Moreover, as the Committee points out, investigations into many aspects of both urban and rural life, such as rates and rating, public and private roads and public ownership of land are essential as a preliminary to the legislation which is already recognized as inevitable.

Since the publication of the Uthwatt Report, the memorandum on compensation and betterment submitted to that Committee by a special committee of the Royal Institute of British Architects has been published in the *Journal* of the Institute. This suggests a method of dealing with this difficult problem which will at the same time be fair to owners and retain the essential of private initiative. Like all other proposals, it insists on a plan as the first essential, and that all land should be deemed to be covered by a planning resolution. For developed land suitable areas can be readily defined for special rating for special improvements, but for undeveloped land the theory of the acquisition of development rights is unacceptable, and if any form of nationalization is to be considered it must not be allowed to be the subject of long years of argument and negotiation.

The really significant feature in the present situation is indeed, as the PEP broadsheet points out, that the question of land ownership and management has been taken to a remarkable extent out of party politics and is being considered on its merits. It is at last possible to tackle the problems of agricultural and urban land on something of a rational basis and to outline the beginnings of a twentieth-century land policy for Great Britain as a whole. This much has been achieved as a result of the PEP report on the location of industry, the Barlow Commission report and the combined effect of submarine warfare, which brought home the folly of neglecting farm and forest land, and bombing, which has at last compelled Parliament to consider extricating the cities of Great Britain from the strait-jacket of an anachronistic system which should long since have been recast.

That the Government is alive to the relation of agriculture and the reconstruction of town and industry is shown by some of Lord Reith's utterances, as well as by Mr. Greenwood in his introduction to the McAllisters' book, or indeed by Mr. Hudson's recent statement in the House of Commons regarding speculation in agricultural land and the issue of a defence regulation to prevent such speculation. That regulation is designed to prevent fresh obstacles arising to the acquisition or scheduling of land for planning purposes, and at the same time to avoid disturbance to the campaign for increased home food production. The scanty reference to such matters in the King's speech at the opening of Parliament, however, may well indicate that it will require all the interest and force of intelligent public opinion to ensure that legislation is not unduly delayed, and that it gives full expression to the hopes which have already been aroused, and uses to the full the opportunities which the War has brought.

Moreover, the third and most recent report of the Royal Institute of British Architects' Reconstruction Committee, on structural building legislation, indicates further directions in which immediate legislation is required. Its first recommendation is the establishment of one national building code for the whole country, formulating, on a scientific basis, standards of stability, fire resistance, and methods, details and materials of construction. There should be in London one central office for general administration with local administration of the national building code. The final and most important recommendation is the setting up forthwith of a national building board as an independent authority responsible to Parliament without being incorporated in the machinery of a Government administration. This board, which might be developed from the Building Research Board and the British Standards Institution, would be responsible for developing a national building research organization, the direction and co-ordination of research on materials and methods of construction and the formulation of the national building code.

These are constructive proposals, though it may be open to doubt whether such a board should not be part of the central planning authority. In this matter of reconstruction and of replanning Britain, however, education, inquiry and action must proceed side by side. Public opinion has already been prepared for advances, and is becoming aware of the importance of land policy and its possibilities. Whether in the war years we are to lay the foundations of a constructive policy of planning town and country side by side, which will use those opportunities and enable us after the War to build a new and healthier Britain, the towns and countryside of which will serve the needs of the new social pattern and contribute to new standards of health and nutrition and living and economic security, depends on whether we bring now to that task the courage, vision and knowledge it requires. The report of the Oxford Conference of the Town and Country Planning Association is a substantial contribution to that task of education. Although it may bring to the scientific worker little in the way of new knowledge, it should at least stimulate him to take a larger share in the task of educating his fellow-citizens, a task which must proceed side by side with the numerous investigations already attempting to gather the detailed facts and knowledge upon which alone a national planning policy can be based.

BRITISH BIRDS

The Handbook of British Birds
By H. F. Witherby (editor), Rev. F. C. R. Jourdain, Norman F. Ticehurst and Bernard W. Tucker. Vol. 5 (Terns to Game-Birds) (Additions and Corrections) (Systematic List and Indices). Pp. xii+356+22 plates. (London: H. F. and G. Witherby, Ltd., 1941.) 25*s*. net; complete in 5 vols., 105*s*. net.

THE final volume of the "Handbook of British Birds" has now made its appearance, and it is pleasant to see that the high standard attained by the preceding four volumes has, if possible, been exceeded in this latest book with its handsome binding, clear print, and excellent illustrations. The editors are to be congratulated on having succeeded, despite the great difficulties of the times, in completing a work on birds which is without a rival not only in Great Britain but also throughout the world.

Terns to game birds are described in the present volume under review, and there is also a carefully compiled list of additions and corrections to previous volumes.

The first bird in this volume—the black tern—is of unusual interest, since, up to the middle of last century and even later, it continued to nest in the Fens of England. It is still seen, each spring and early summer, frequenting its former haunts for a few days while on passage to Belgium and Holland, Denmark and the Balkan States.

The common tern at its summer haunts is a bird of two distinct habits: it may nest in large colonies on the coast, or may breed in pairs along the shingly stretches of the Dee, Spey and other Highland rivers. On the Dee I have seen it nesting beyond Ballater—that is, as the river flows, fifty miles from the sea. A point which I have noticed is that these single terns are much more timid at their nesting haunts than the colonies which nest on the coast, and will not fly down to their eggs so long as they believe a human observer to be in sight of them. One difference between common and Arctic tern is the colour of the bill. In the common tern it is orange-red with black tip: in the Arctic tern it is blood-red throughout, and has no black tip. The Arctic tern's alarm note is shorter and harsher than the corresponding call of the common tern, and when on the ground the Arctic tern is seen to be shorter-legged.

The sudden flights out to sea of common terns (p. 29) during the nesting season is discussed. These periodic flights, during which the clamour of the nesting colony is suddenly hushed and all the birds fly in complete silence out to sea a little way before swinging in again and returning, still in silence, arise from some cause not yet understood. G. and A. Marples in their "Sea-Terns" (pp. 169—172) attribute the flights to sudden fear, of obscure origin. Arctic terns also make these flights, and so do kittiwake colonies. My own impression is that these aerial excursions are due to a sub-conscious migratory impulse. Certainly the flights become more frequent as the nesting season advances and as the August day approaches when, leaving belated eggs and immature young of various sizes to perish, the colony as one bird rises into the air and sets out towards the south.

The black tern is easy to identify, but there are many bird students who are not sure of the differences between common and Arctic tern. The full and careful descriptions of these two species, and the means of distinguishing them, are therefore valuable. The same remark applies to the rare roseate tern.

In the auk section of the volume the authors have been at pains to work out the distribution (p. 156) of the ringed or bridled variety of the common guillemot. In the eastern Atlantic there is a general tendency of increase in the bridled variety northward, and to a less extent westward, with some exceptions. Thus in the Portuguese colonies of these birds bridling is not recorded, while in France the figure is as low as 0·1 per cent. In Heligoland and the Baltic the figure is mainly between 1 and 2 per cent, as in the southern British Isles. In Shetland colonies this figure is greatly increased, and a further increase is found in the Faeroes, where the bridled variety form 34 per cent of the colonies. On the Westmann Isles, off the south coast of Iceland, bridled guillemots form 52·7 per cent of the colonies, but off the north of Iceland, on Grimsey, the figure falls, curiously enough, to 8·7 per cent.

Of the great autumn migration of the common guillemot south-westward through the Minch something might be said, the birds passing daily in thousands throughout the month of October.

The black guillemot (p. 163) would appear to be more sedentary in habit than the common guillemot. To the 'food' of this species might be added small conger eels and small flat fish.

A considerable proportion of the volume is devoted to the gull tribe.

In the account of the distribution of the large Arctic-nesting glaucous gull (p. 109), I am reminded that I have seen this gull on the River Dee in Aberdeenshire when fishing in early February at the opening of the salmon season. At this time of the winter a considerable number of kelt salmon have died after spawning. These fish are lying on the river banks, or in shallow water, and great black-backed gulls habitually enter the river valley to feed on them. One day I saw, with the great black-backs, a large white gull which could have been no other than a glaucous gull, with which species I had been familiar in Spitsbergen. I suspect that this gull, when dead salmon are numerous, ascends the lower reaches of Highland rivers more often than is supposed. In the account of the gulls the difference in plumage between the British lesser black-backed gull and the Scandinavian lesser black-backed gull is clearly described (p. 96). In the Scandinavian species the mantle is slate-black ; in the British species slate-grey. During the years I had my home at Aviemore I used each spring to watch a migration of lesser black-backs flying, day after day, sometimes in considerable flocks, sometimes singly, north-east down the Spey valley. This migration continued through April and well into May, and the birds were presumably crossing from the Atlantic seaboard towards the Moray Firth basin, before travelling over the North Sea to the coast of Scandinavia.

A slight amendment might be made (p. 81) in the elevation at which the common gull is found nesting in Scotland. For "over 1,500 feet in Scotland" might be substituted "up to 3,000 feet". There is a loch on the White Mounth where a colony of these gulls nests at a height of 2,800 feet, and an occasional pair nests on a small loch higher up the hill, on the 3,000 feet contour line. These common gulls feed their young largely on ptarmigan eggs, which they steal from the nest and carry in their bills to their loch. The discarded egg-shells may be seen in the shallow water. This high loch is usually hidden in snow and ice in April, and the gulls pay several visits to it before they are able to settle here.

In the very full and thorough account of the Scottish ptarmigan (pp. 228—233) it is stated that the cock ptarmigan stands on guard when the young are hatched. The observer who makes this statement has great experience, but my own observations (I have seen many scores of ptarmigan nests and young broods) is that the male bird disappears from the nesting site the day the young leave the nest—and they leave it if the weather be fine an hour or two after they are hatched. My wife and I have photographed ptarmigan broods a few hours old, and although the hen has shown intense anxiety, the cock has never appeared. I mention this, for it has always seemed to me that the habit of a most devoted mate in suddenly deserting the newly hatched young is strange and unusual.

Ptarmigan, like red grouse, cover up their eggs before the clutch is complete and the hen bird begins to brood, and sometimes a few white feathers adhering to this covering give away the nest.

Ptarmigan are found in various forms throughout the world, and when I was in Iceland recently with Mr. J. C. Harrison (who has an admirable plate of skuas in flight in the volume under review) I was interested to see that the Iceland ptarmigan frequents the glens and low country, where it may be seen from the road. We both remarked that the wing beats of the Iceland ptarmigan were much more rapid than those of the Scottish ptarmigan, and that the flight recalled that of a partridge rather than a ptarmigan.

No one interested in birds can afford to be without the fifth volume of this standard work.

SETON GORDON.

THE MESSAGE OF THE GARDEN

Green Enchantment

The Magic Spell of Gardens. By Rosetta E. Clarkson. Pp. xx+328. (New York: The Macmillan Company, 1940.) 12*s*. 6*d*. net.

REALLY good enchantresses have always had more than one string to their bow, though those who escape their snares would probably put it the other way about. When they were young, enchantresses could afford to rely entirely on their charms for the bewitching of man ; but as they began to grow old and their charms began to fade, they took to casting spells. For that they had to go to the fields and hedgerows and gather green plants in the moonlight for the raw material out of which all the best spells are made. If enchantresses werel ucky and escaped a watery grave, their increasing years turned them into witches. Bent double by bending over ditches and riding broomsticks, they could no longer go far afield to find the herbs that specialized in being magical. That did not stop the witches, however, for they could find all the magic herbs they needed in the garden. From being used so often for spells, the plants grew more potent, and presently the garden itself became still more the home of magic than it had been before—a place of green enchantment.

No one can go into the garden now—be it large or small, wild or formal, neat or unkempt, well or ill planned—without falling under its spell ; at all events they will not after they have been taken there by Rosetta E. Clarkson and have heard the stories she has to tell of garden green enchantment.

How wise she is to begin with a sort of exorcizing to restore its good name to the garden. She says nothing at first about the witches and the spells and charms. She starts off with the gentle monks and their horticultural acolytes, and shows them at work in the monastery garden : planting herbs for healing, odorous plants near the sick room windows to appease the suffering inmates, lilies and roses and flowers of every kind in the sacristan's garden—these for the altar and for garlands in processions on holy days; they named it paradise. Even when urban popes and cardinals told them not to, the simple monks went on growing the flowers all the same. They made walled gardens for fruit trees and they made vineyards too. Is there not still a street corner called the Vineyard near the Abbey Gates at Abingdon ? Nor did the monks forget the vegetable garden. They planted it not only for summer use but also for food in the long winter.

Then when the monasteries declined, it was the wicked barons who took to gardening. They filled in their moats and made gardens there. They had to do something because Henry VII would not let them fight any more, nor use their castles as strongholds in his defiance.

Throughout these centuries plants from all over the world came crusading to England, and having conquered it settled down in our gardens. What the castle grew the cottager would have, and many a plant which died on the squire lived on in the cottager's plot. Why! it may be that to-day, Madonna lilies flourishing in a sunny corner of the cottage garden have been growing there since Tudor times : still magical in their immortality.

When printing came, everybody began to write about plants, and the great days of the herbalist began. Books by the score, editions by the dozen, sometimes by the hundred, were written and printed and even read.

All these things and many more are to be learned from Rosetta Clarkson's story. She shows you the plants they grew. Tells the lovely names the common people called plants by—no one except the very great was afraid of being called sentimental then. You can see the tools that were used. You can wonder at the infinite variety of sallets in the old gardens now dwindled to the solitary lettuce in ours, the flowers that went to conserves and preserves to give plenty of vitamin P on winter's table.

It is only towards the end of her story that the author opens a little wicket gate creaking on its hinges and leads her enchanted companions into the witches' garden ; lets you see the fumitory that wards off the evil eye, the rosemary for remembrance, the woodbine that has bewitched so many cattle, the elder that makes warts go away and the parsley with seeds that have to go nine times to the devil before they consent to germinate. Every witchery that ever was is still there, preserved for ever in the names the plants bear.

When she has finished and you awaken from the enchantment, there seems to come into the mind a new understanding of the ever green enchantment of gardens. There and there only may be got glimpses of the country—all the countries of the world—and of the forgotten ways of country life. There pleasure and utility go hand in hand, united, made one, so that for the moment life becomes a whole, as it never can be in cities. It beckons man back to Nature, and though urban folk ignore the invitation they feel the summons in their bones ; recognizing, if only faintly, that the problem facing all societies is how to remain urban without losing the last traces of rusticity. While there is life—garden life—there is hope, hope that the unspoken warning of the garden may be heeded before it is too late.

F. KEEBLE.

CHEMICAL ENGINEERING EXPERIMENTS

The Applications of Chemical Engineering

Edited by Prof. Harry McCormack, in association with E. W. Comings, J. C. Elgin, W. L. Faith, O. A. Hougen, Joseph H. Koffolt, Harry McCormack, R. A. Ragatz, J. H. Rushton, Henry T. Ward, J. C. Whitwell, James R. Withrow, Lincoln T. Work. Pp. x+431. (London : Chapman and Hall, Ltd., 1941.) 21*s*. net.

THE title of this work might indicate that it deals with the application of chemical engineering theories to the solution of industrial problems, but this is not the case. It is, actually, a comprehensive collection of experiments for the use of students. This, however, is an inadequate description ; the volume represents the outcome of the labours of a succession of committees which since 1929 have been collecting and arranging material suitable for a practical course, and the result is a detailed description of some seventy-five experiments classified under eleven main headings. Each heading forms a chapter written by an expert and revised by the committee in order to obtain uniformity of treatment. In a typical chapter the first pages are given up to a concise outline of the fundamental theories involved and the rest is devoted to the experiments, numerous specific references and a general bibliography of the subject being included.

It may be said that there are two main ways of presenting a practical exercise to a student. According to the first, he is given a piece of apparatus complete with all accessories and an instruction sheet detailing the object of the experiment and the exact method of performing it. According to the second, the object is given, but it is left to the student to think out what measurements must be made and what are the most suitable instruments to use. There is little doubt that the second method is of far more value for developing originality and self-reliance than the first, but unfortunately, it may require an excessive amount of time and more attention on the part of the instructor than can be given. A compromise depending on the ability and experience of the student is probably the best solution. His early experiments may be conducted according to instruction sheets to familiarize him with general experimental technique, but as he progresses, more and more details may be omitted, so that finally he becomes dependent on his own initiative. It has been found in Great Britain, more particularly with larger apparatus such as stills and evaporators, that instructions can be cut down to a mimimum provided that two or even three students are assigned to the same experiment so that they may make simultaneous measurements and also discuss problems which arise during their progress.

The experiments dealt with in the book, while in nature similar to those conducted in the larger chemical engineering laboratories in Great Britain, are described with a wealth of detail which makes possible the adoption of the first of the above methods should it be required. A drawing of suitable apparatus or plant is given and a list of measurements which can be made. This is followed by instructions for performing the experiment and a set of typical results, with complete calculations. Experimental details which might escape attention are emphasized and the underlying theoretical principles are referred to at frequent intervals.

With regard to individual chapters, the first, dealing with the measurement of temperature, is an admirable article on certain aspects of precision thermometry, including a few experiments reminiscent of the elementary physics laboratory, but it lacks reality, and its connexion with the practical requirements of chemical engineering is not always obvious. For example, a student reading the description of a platinum thermometer would have no idea of the size of wire with which it is wound, or its resistance. No reference is made to the errors due to thermocouple sheaths insufficiently immersed or to thermal conduction along thick pyrometer wires. Black-body errors are mentioned, but it is left to a later chapter to give an indication of their magnitude, while the measurement of the temperature of a gas is confined to a brief note on one type of thermocouple. In practice, electrical measurements are rarely made on simple slide-wire bridges, and students should learn how to operate special instruments from a study of the wiring diagrams ; the two examples given are not very clear. It is suggested that this chapter might be recast.

The following chapter dealing with the flow of fluids gives a number of useful assemblies of apparatus suitable for most requirements ; some of the diagrams are perhaps a little sketchy and there is less detail than is to be found in subsequent chapters, but the information given is adequate and a student who had conducted all the experiments would be well equipped for dealing with fluid flow measurements on industrial plant.

Some subjects lend themselves more readily than others to simple experimental investigation, and the flow of heat, a matter of outstanding importance to the chemical engineer and the subject of the next chapter, is fortunately one of the former. Professor McCormack's treatment is most lucid, and fundamental principles are repeatedly emphasized throughout the mass of experimental details. One point to which more attention might have been given, if only because it is frequently neglected by designers, is the great increase in liquid film coefficient obtained by the use of high liquid velocities. This chapter is perhaps the most outstanding in the book, but a similar high standard is maintained in the remaining eight, which are devoted to unit processes. If any of these can be specially commended they are those dealing with distillation, drying of solids and gas absorption. This is not so much for any special features but because they offer more scope for experimental treatment than the rest. Whether the equipment required belongs to the category "simple" as described in the preface, or not, is perhaps a matter of opinion, but there will certainly be general agreement that the practical side of chemical engineering cannot be studied without adequate plant. A second claim made in the preface is that every experiment can be accomplished in a single four-hour period. This may be correct, but the desirability of rushing through what is in some cases a fairly elaborate series of measurements following upon preliminary adjustments, is open to question.

For those who are contemplating the establishment of a chemical engineering laboratory the book will be found invaluable. The experiments described are so numerous and cover so wide a field that a judicious selection, modified to suit the available apparatus, should afford ample material for a useful course. Those who already possess a laboratory will find many suggestions, either for utilizing their existing equipment in novel ways, or for adding to it and thus extending the scope of their practical work. No text-book on these lines has been produced hitherto and the Society for the Promotion of Engineering Education is to be warmly congratulated for a very valuable contribution to chemical engineering.

H. E. WATSON.

GEOLOGY AND GEOLOGISTS IN THE NATIONAL WAR EFFORT

By PROF. H. H. READ, F.R.S.

Imperial College of Science and Technology

THERE appears to be considerable divergence of opinion among professional geologists in Great Britain as to the extent to which they and their knowledge can be used in war. Some hold that hundreds of geologists could be employed in the civil defence and armed forces; others protest that saturation would be reached by the employment of a score or so. Whatever may be the truth of this matter, however, all are agreed that the utilization of geological knowledge in the war effort has up to now been singularly haphazard. It is, of course, possible that a considerable proportion of the cases of the successful use of such knowledge never becomes public, while certain scandalous examples of neglect of geological information achieve, on account of their news value, a disproportionate notoriety. Still, if there were but one case of such neglect, the geologist would be entitled to lift up his voice. When he is officially informed that a sum approaching half a million pounds has been wasted through this cause at one aerodrome site alone, he must be pardoned if he becomes speechless, and especially so since, though he may faintly hope that those officials responsible for this waste have been liquidated, he is secretly sure that they have been promoted to posts with still greater possibilities.

As Prof. P. G. H. Boswell has pointed out in his presidential address to the Geological Society, issued on September 30, the fundamental reason for this haphazard utilization of geological knowledge is the lack of awareness on the part of the general public of the content of the science. The ignorance is, of course, especially profound among the politicians and the higher Civil Servants, while among scientific men it is often deplorable—a result in their case arising from a devotion, inculcated in the schools and fostered by examination requirements, to the unholy trinity of mathematics, physics and chemistry. One would have expected, on the grounds of value for money alone, a fuller utilization of geological knowledge which, in predominant proportion, has been accumulated and is being correlated and curated through the use of public funds of one kind or another. There is, however, little to be gained by elaborating this jeremiad, and we can with greater profit turn to the contemplation of such uses as have been made of geology and geologists in the war effort.

Large-scale industry, the sustainer of modern mechanical warfare, is founded upon iron ore and the solid and liquid natural fuels. Vital for the full development of its power, however, is a great variety of strategic mineral products, such as the alloy metals, the important non-ferrous metals, and a group of non-metallic minerals chiefly of a refractory or abrasive character. Further, food is a munition of war, and in consequence the mineral fertilizers are of strategic importance too. This fundamental dependence of industry upon mineral products becomes a lively topic during a time of mechanical warfare when it is impressed upon the political and Civil Service hierarchy that minerals are not evenly distributed among the nations, that supplies of vital raw materials are liable to interruption or even stoppage and that, in any event, minerals are bulky commodities usually requiring lengthy transport. A modern State, bent upon modern war, would naturally accumulate reserves of strategic minerals sufficient for the estimated duration of the conflict. We may be sure that the Axis has affected this obvious insurance, and that prophecies of an Axis shortage of oil, of some alloy metal or of some other strategic mineral product are liable to falsification.

An effort for autarky, or for the transformation of a peasant State into an industrial one, depends for success upon the discovery within the borders of the State of mineral resources of suitable size, character and variety. In this connexion, it may be recalled that thousands of geologists have been employed in mineral prospecting and development in the U.S.S.R. during the last twenty years. Their efforts have had remarkable successes; there have been notable and constant increases in Soviet mineral production, both in amount and variety. In NATURE of October 25, Prof. A. E. Fersman recorded that during the last quarter of a century, 75,000 new mineral fields were discovered in the U.S.S.R., that the known coal resources had been increased ten times, the resources of iron ore thirty-three times, and of lead and copper more than ten times. Fundamentally, therefore, the heroic Soviet resistance is possible because of the field-work of the Soviet geologists. It is my opinion that the most important use of British and American geologists in the war effort is to be found in the continuance of their jobs, often unheroic, of finding new mineral deposits and of developing maximum production of the required grades from these and the old fields. If the Allies hold on, it is comforting to reflect that the mineral resources of the British Empire, the U.S.S.R. and the United States are complementary to an extraordinary degree, while those of the Axis are thoroughly lopsided and, in the cases of the two junior partners, practically non-existent.

The interruption of supplies from overseas and the difficulties of transport have naturally led to renewed investigation, followed by development where possible, of native British mineral resources. In this work the dominant part is played by H.M. Geological Survey which, during its century of existence, has accumulated a vast store of information concerning mineral possibilities in Great Britain. The resources of coal and iron ore, the basic requirements of industry, have continued to be investigated in detail, while much attention has been directed to the discovery and workability of such ancillary metals and non-metallic minerals as this country can supply.

The results of a number of these investigations are given in the War-time Pamphlets issued by the Survey, which deal, in this connexion, with iron ores of various kinds, felspar, diatomite, dolomite and brucite-marble, silica-rock, phosphates, talc, chromite and limestones. This list, of course, by no means covers the complete field explored. It is gratifying to learn that production is taking place from mineral deposits discovered and investigated by the Survey. One success that may be mentioned is the find of a sand in Morvern, Scotland, suitable for optical glass and equal in quality to the best Continental sands, which is being worked on a considerable scale. In this type of investigation, the Survey is often helped by university and other geologists who have the advantage of detailed local knowledge. Such geologists, too, are being consulted on special problems of supply by Government and other bodies. In addition to investigations such as those mentioned, the

Survey deals with routine inquiries, some of which entail lengthy researches. A service of a similar nature dealing largely with inquiries from the Dominions, India and the Colonies is provided by the Mineral Resources Department of the Imperial Institute. This Department publishes monographs on economic minerals and valuable statistical reports on world mineral production.

The staff of the Geological Survey, however, is limited in number, its members rarely reside for long in any particular place, and they are unable, therefore, to record the innumerable temporary sections and exposures that are constantly being produced. The local geologist, whether university or lay, has opportunities of acquiring a detailed knowledge, especially of the superficial deposits, which is denied to his Government colleague. It is to the local geologist that the civil authorities, if necessary through the offices of the regional commissioner, should turn for geological information on such matters as the proper siting of shelters, supplies of sand, and questions of a kindred nature. So far as I am aware, this has been done in few cases; the results of this neglect can be seen all over the country. A similar absence of consultation between the military authorities and local geologists is indicated, for example, by the flooding of military works, the perilous position of certain tank blocks especially along rivers, and the instability of costly excavations. It is happier to record that in a few cases this desirable liaison has been established. Good work was done by some local geologists in indicating sources of sand for sandbag-filling in the early days of the War. Moreover, hundreds of thousands of pounds were saved in transport costs in London alone by following advice on the location of sand deposits given by the Geological Survey.

A very important war-time activity of the Geological Survey is connected with water supply, and many of the War-time Pamphlets deal with supplies from underground sources for various parts of the country. Movements of population, the formation of great military camps and aerodromes, and the construction of immense factories all raise problems in water-supply. Time was when a camp site was decided upon and then a water-supply demanded, but I understand that this procedure has now been changed. It is obvious that an accurate assessment of the present supply from underground sources, of emergency and even long-range supplies, has to be made, and especially in the so-called invasion areas. Piped supplies are liable to interruption by enemy action, and so the storage of water for fire-fighting in vulnerable districts may give rise to geological inquiry.

At the beginning of these remarks, I recalled the case of the scandalous neglect of geological advice at an aerodrome site, and I repeat that as complete a knowledge as possible of the geological conditions, both as regards water supply and foundation factors, at sites projected for costly camps, aerodromes and factories, is an obvious precaution. The Geological Survey and non-Government geologists are engaged in a certain amount of preventive work along these lines.

Readers of the more popular Press may have seen very remarkable accounts of some of the underground factories, stores and the like which have been constructed. Before the expenditure of vast sums of money on these great mining and engineering works, with their attendant housing and transport schemes, it is clearly a matter of common-sense to study in detail the prime control, the nature of the rocks and their arrangement. Here, again, the geologist has been utilized. The roughness of the geological story of Great Britain has resulted in our possessing a great number of suitable rocks suitably arranged for this purpose. A similar foresight is necessary in the construction of deep air-raid shelters and, again, most of our large towns have a fortunate geological past. At this point, non-geologists should ponder as to why London has its Underground, and draw a little comfort in these hard times.

What has been said above deals largely with the use, or non-use, of geological knowledge, but it has also been suggested that the best use of the geologist is to let him carry on with his usual work. This suggestion has not always been followed, and often it is the geologist himself who decides on a change of occupation. In certain branches of the Forces, a geological training is an advantage. All geologists can read maps and most can make them, some are expert drillers and others are familiar with mining and excavation methods. Men who have earned their living for years by the interpretation of aerial photographs should be employed in similar work in the Services. I have heard of an ex-geologist airman who finds his way about above England by his geological knowledge. There is a niche somewhere in camouflage for a geologist who will prevent the breaking of all geological rules in one small scheme, just as in happier times Hollywood might be persuaded to hire a geologist who would make sure that a film alleged to be in a Jerusalem setting would be set in Jerusalem geology, and not in that of California.

Such are some of the ways, then, in which geological knowledge and geologists are and are not being used in the war effort. The full employment of both can follow only from an adequate realization by the directorate of the possibilities of service.

MECHANISMS OF VISION

By PROF. SELIG HECHT

Department of Biophysics, Columbia University

THE symposium on visual mechanisms held on September 24 during the Fiftieth Anniversary Celebrations of the University of Chicago brought together some of the diverse methods and points of view found in the study of vision. Of the eight papers, three were concerned with the structures, materials and energy relations of the eye itself; one considered vision merely as an indicator of the state of the nervous system under anoxia; while the other four explored the relations between sensory phenomena and the central nervous system.

The morning session began with a report by Prof. Selig Hecht on the minimum energy required for vision. New determinations made under the best physical and physiological conditions yield values between $2\cdot2$ and $5\cdot7\times10^{-10}$ ergs, which correspond to 58 and 148 quanta of blue-green light (510 $m\mu$). This is at the cornea. After corrections for reflexion from the cornea, for scattering and absorption by the ocular media, and for transmission by the retina, the range of 58–148 quanta at the cornea becomes 5–14 quanta absorbed by the retina. Since the stimulated retinal area contains five hundred sensitive elements, a 2-quantum absorption by any one element is unlikely. Therefore, in order for us to see, only one light quantum need be absorbed by each of 5–14 retinal rods.

Because this number of events is so small, it may be derived from an independent statistical study of the relation between the intensity of a light flash and the frequency with which it is seen. Such experiments yield values of 5–7 for the number of critical events involved in threshold vision. Biological variation does not alter these values essentially, and the agreement between directly determined values and those derived from statistical considerations may be considered significant.

The results bear on the nature of the fluctuations shown by an organism in its response to a stimulus. The assumption has generally been that the stimulus is constant and the organism variable. The present considerations, however, show that at the threshold it is the stimulus which is variable and that the nature of its variability determines the fluctuations encountered between response and stimulus.

The light-sensitive substance of the retinal rods is visual purple. Prof. Arlington C. Krause, of the University of Chicago, has prepared enough visual purple so that common chemical procedures may be used for its study. He reported that visual purple consists of 50–65 per cent protein and 35–50 per cent lipid. The protein, though not well characterized, is conjugated with a complex lipid of fairly large molecular weight. The lipid contains nitrogen, sulphur and phosphorus fatty acids, and an unsaturated chromophore group, which may be carotenoid but is probably neither vitamin A nor carotene.

Several new substances can be isolated from the retina. Provisual red absorbs light between 340 and 416 mμ, gives an antimony trichloride reaction, and on hydrolysis yields fatty acids and visual red. Visual red absorbs only in the violet and ultra-violet, and also gives an antimony trichloride reaction. The yellow colour of bleached visual purple is due to visual yellow and indicator yellow. Visual yellow contains no nitrogen, phosphorus, or sulphur, and is insoluble in water. Indicator yellow contains both nitrogen and phosphorus, and is water-soluble.

Prof. Krause emphasized the similarities in light sensitivity and structure shown by visual purple and by cyanine dyes used for sensitizing photographic emulsions.

One of the outstanding characteristics of the central nervous system is its high metabolism and its great sensitivity to the lowering of the oxygen tension of the blood. Since visual impulses ultimately register in the central nervous system, visual function should be disturbed under anoxia. Prof. Ernst Gellhorn, of the University of Illinois, reported just such changes in brightness discrimination, visual acuity, colour perception, visual fields and negative after-images, and emphasized the rapid reversal of the effects by inhalation of oxygen. Since all these effects have in common the sensitivity of the nervous system to anoxia, it is concluded that they are an expression of this common factor. (It should be recalled that the retina also has a high metabolism and is sensitive to oxygen; indeed the recent work of Craik shows that visual function may be disturbed by local anoxia at the eye.)

Prof. Gellhorn presented evidence to show that the central nervous system possesses a progressively increasing sensitivity to anoxia in proportion as one goes to higher levels. This is illustrated by the effect of anoxia on eye movements: those which are elicited reflexly are less affected by anoxia than those which are cortically determined.

The final morning paper was by Prof. Heinrich Klüver, of the University of Chicago, who summarized the difficult and beautiful experiments with Rhesus monkeys made before and after removal of the striate cortex. By use of the pull-in technique, it was possible to measure the visual capacities of such animals in considerable detail. The results show striking differences between operated animals in dim illumination and in bright illumination. Dark-adapted animals without any geniculo-striate system are still able to discriminate the brighter of two stimuli under a variety of modes of presentation of the two stimuli. The just recognizable brightness fraction $\Delta I/I$ lies between 0·23 and 0·29. The same differential fraction is obtained for area discrimination of equally bright surfaces, and for distances (squared) of otherwise equal fields. This indicates that it is the total luminous flux which is recognized, rather than its distribution in space. A difference in total amount of light is distinguished whether it is achieved by distance or by area or by brightness variation. Form perception is thus permanently lost.

All this is at low illumination and involves only the dim vision of the duplicity theory. Indeed the effectiveness of the spectrum bears this out, because it yields a luminosity function similar to the scotopic luminosity curve of the human eye. For higher illuminations involving light adaptation, the operated animals lose all trace of differential response.

In the normal monkey, recognition of differences in brightness or area or colour are not seriously affected by the way in which the stimuli are presented. It is as if these properties remain relatively constant despite marked changes in stimulus constellation, and thus provide the animal with a stable visual world. The removal of the geniculo-striate system seems to eliminate these constancies irretrievably.

The afternoon session was opened by Prof. Theodore J. Case, of the University of Chicago, with a paper on occipital alpha waves. Under normal conditions, these rhythmic brain potentials from the two sides are in phase and approximately equal. Occasionally persons appear in whom there exists a gross difference in size of the occipital waves from the two sides, whereas the frontal alpha waves are equal. Such individuals possess lesions in the occipital or temporal lobes, usually involving the optic radiations that pass through these structures, and therefore causing partial blindness (homonymous hemianopsia) on the side opposite the lesion.

Examination of more than a hundred persons with supratentorial lesions showed that whenever the optic radiations were involved, there was always a substantial difference between the occipital alpha waves on the two sides, so much so that a gross difference in occipital waves may be considered almost a diagnostic sign of occipital or temporal lobe lesions. Since an interruption anywhere in the geniculo-calcarine pathway interferes with the occipital alpha waves of that side, and at the same time destroys vision, it may well be that the alpha waves actually exist in the optical radiations as an intrinsic rhythm upon which impulses from the visual organ impinge to form patterns for the mediation of vision.

Following this paper, Dr. S. Howard Bartley, of Washington University, presented some correlations between vision and neurophysiology. First, he compared the potential changes in the optic nerve on stimulation of the eye with the known corresponding sensory experience. A short, weak flash of light results in a simple optic nerve discharge without subsequent changes. In vision this is registered as a simple flash of light. With a longer or more intense flash, the optic nerve record is a series of fairly regular waves following the simple *on* response. Visual experience reports this as a brief period of just distinguishable flicker. With a still longer or a more intense flash, there appears a prominent secondary wave which replaces the train producing the flicker; it and the *on* response yield the paradoxical experience of seeing two flashes. The secondary wave drops out as intensity or duration is increased, and visual experience loses its duality.

When the cortical response is recorded, the results are not so clear, and frequently involve interpretation. The most interesting fact is that a strong repeated stimulus may force the cortex to set up a rhythm in tune with the stimulus.

The paper by Prof. Stephen Polyak, of the University of Chicago, was a brief summary of material since published as a volume, "The Retina", in the Anniversary Series of the Chicago University Press. The essential point is that the complex structure of the retina agrees with the complex nature of the visual process. There are at least thirteen different types of neurons in the retina arranged in three levels: the photoreceptors (rods and cones), the analysers and association neurons (bipolar cells, horizontal cells and probably amacrine cells), and the integrators (ganglion cells).

The relations among these elements are complex and stable, and are at least thirty-five in kind. Some indicate an analysis of impulses from the photoreceptors; others suggest 'final common path' functions; while still others may even be inhibitory. Besides the perception of light and of colours, the retinal structures lend themselves to an interpretation of the various aspects of space perception, in terms of the degree of individuality in the connexions of the three components.

The symposium was closed by Prof. K. S. Lashley, of Harvard University, who proposed a new theory of cerebral organization. Animals are capable of perceptual generalization. When trained to differentiate on the basis, say, of specific sizes, they carry this over to a variety of visual arrangements. An object retains its essential form though we view it from different fixation points. The problem is that while nerve impulses are transmitted over definite pathways, behaviour seems to be determined by masses of excitation within general fields of activity without regard to particular nerve cells.

The exact topographical projection of the retina on the striate area may not be primary, because the olfactory sense is also accurately projected, yet it does not correspond to olfactory space. It may be that the geometry of nervous integration is quite different from the geometry of the stimulus.

The surface of the cortex contains connexions which permit the passage of activity in all directions. From a single focus, excitation may spread over the whole cortex, and because of the refractory period this spread will be wave-like. From several foci, interference patterns will be formed extending over the whole cortical area. Thus a given retinal configuration can produce a characteristic pattern of standing waves on the cortex which then forms the basis for its recognition.

Motor responses also are generalized. A rat which has learned a maze can follow it with unpractised muscle groups; thus a rat with a cerebellum lesion will roll rather than crawl through the maze successfully. The essential equivalent of visual perception is thus translated into an essential equivalent of muscle function. This means a revision of current notions of sensory motor organization. There is demanded a much more diffuse and widespread connexion between sense organ and motor neurons, a connexion in terms of an overall pattern perhaps such as is suggested for sensory organization.

RECONSTRUCTION IN CHINA

By ZING YANG KUO

Director, China Institute of Physiology and Psychology, Chungking

CHINA has already begun to plan her national reconstruction after the War. But given good plans for Chinese reconstruction, and given sufficient capital and raw materials, China may not be able to carry out her programme of reconstruction successfully and effectively unless she has adequate supply of scientific men, engineers and technicians. At present there is already great shortage of trained personnel in various fields, especially in science and technology. Due to the lack of library and laboratory facilities as a result of destruction by the Japanese, and also to the insufficient number of first-grade professors in China, the training of scientific and technical personnel for cultural and economic reconstruction in China will depend, more than ever before, upon sending students to study in American and British universities. Unfortunately, since the outbreak of the war in China, the number of students studying in the United States and Britain has been reduced by more than a half, while very few remain on the European Continent. Unless a well-planned programme for training men and women for the tasks of reconstruction is worked out well in advance, the shortage of scientific and technical personnel will be very much more acute when the War ends and reconstruction in industry and agriculture is begun.

Such a programme for training scientific and technical personnel for China calls for the active co-operation and assistance of Great Britain and the United States. It means that for many years to come, before the Chinese universities are re-equipped and brought up to modern standards, and have sufficient good teaching staff, Chinese students will continue to be sent by hundreds to the United States and Britain for scientific and technical education; it means that many American and British professors will have to be invited to teach in Chinese universities.

It was with this purpose in mind that I am visiting Great Britain and the United States as the representative on education of the Chinese Government to seek for co-operation and assistance from these two countries. As the project of inviting visiting professors to teach in Chinese universities cannot be carried out before the universities are sufficiently re-equipped, my negotiations in Great Britain have been confined to the arrangements for sending Chinese students to study in British universities or to obtain experience in factories. There are two parts in this project: (1) sending graduate students with two or three years of practical experience in China, either to study in a British university or to practise in a British factory; and (2) sending a number of Chinese university teachers, especially teachers of science and technology, to Great Britain, to refresh their learning and to get acquainted with the latest developments in various scientific and technical fields.

British intellectual and industrial leaders have responded sympathetically and generously to my proposal in connexion with the first part of the project. If the arrangements so far made for sending Chinese students to be trained in Great Britain are carried out with success, I shall, in the near future, take up negotiations concerning the second part of the project.

American educational and industrial leaders have also responded to my proposal with sympathy and enthusiasm. It is hoped that through exchange of information and mutual understanding, the efforts of Great Britain and the United States to assist China to rebuild her culture and to train young minds for her national reconstruction can be coördinated, and that greater cultural co-operation between China and the English-speaking nations can be secured.

I have laid great stress on the importance for the national reconstruction of China after the War of training scientific and technical personnel. This must not be taken, however, to mean that other aspects of cultural studies, such as fine arts, philosophy, literature and the humanities, etc., are to be neglected. On the contrary, such subjects will receive due attention in the programme of cultural reconstruction in China. In fact, it is my hope that even in training young scientific workers and engineers each student would acquire a good cultural background together with his technical education.

OBITUARIES

Viscount D'Abernon, P.C., G.C.B., G.C.M.G., F.R.S.

EVEN in peace-time, there is a constant but subdued lamentation on the part of scientific men that their subject receives but scant consideration by politicians and others controlling public affairs in formulating and executing public policy. In war-time such lamentation is less subdued. When, therefore, a great public figure has used the weapon offered by science to the great benefit of the State, it is only right that his death should call for more than a passing reference. Viscount d'Abernon, whose death at the age of eighty-four occurred on November 1, was a man who, without any special training in science, came to have a great belief in the part it might play in government. He was a man of remarkably wide interests and achievements, a statesman but not a politician, and a man of the highest culture, who knew, or wished to know, the best that had been thought and said in the world. He had also the keenest appreciation of art, especially of painting and the drama. Nothing human was foreign to him.

It will be remembered that, in the War of 1914–18, alcoholic intoxication became an enormous problem, of such magnitude indeed that it interfered greatly with the production of war material. To meet this situation, Mr. Lloyd George set up the Central Liquor Control Board and made Lord d'Abernon its chairman. The object was to find any or every means, short of prohibiting the production and sale of alcoholic liquor, which could reduce the evil to a minimum. The success obtained by this Board has never been really appreciated, but those who remember the extent of drunkenness in pre-war days cannot but conclude that the Liquor Control Board conferred one of the greatest social blessings on Great Britain. This inappreciation of valuable work is often seen when the state of man is changed for the better. Most medical men are very familiar with the phenomenon. They know only too well that, when a dramatic method of treatment is discovered, so that the dying or moribund are restored to health, this and its discoverer are hailed with great enthusiasm. They know equally well that, when a disease is eliminated by the discovery and application of a preventive method, there is no excitement, the change passes unnoticed and is taken for granted. This is what happened as the result of Lord d'Abernon's work in the case of alcoholic intoxication. The country has become relatively sober and the accursed social conditions due to widespread drunkenness have practically disappeared without comment.

Those with intimate knowledge of the Liquor Control Board know that Lord d'Abernon was not a figure-head as its chairman, but that he played the leading part in its deliberations and activities and gave up all his time to its work. The masterly way in which he controlled a body, which included brewers, clergy, politicians and Civil Servants, and obtained from them unanimous decisions, was a remarkable achievement. Confronted as he was at all stages by partisan statements on the action of alcohol, he decided that the only way of getting the truth was to appoint a body of scientific men in an advisory capacity. This body included among others Prof. (now Sir Charles) Sherrington, the late Prof. A. R. Cushny, Dr. (now Sir Henry) Dale, the late Prof. W. McDougall, and Prof. M. Greenwood. They gave careful consideration to the whole question of the pharmacology and toxicology of alcohol and proceeded to write the well-known book "Alcohol: its Action on the Human Organism". Where there were outstanding gaps of practical importance in knowledge, such as the relative intoxicating properties of concentrated and dilute alcoholic beverages, or the rate at which alcohol disappears from the body, or the kind of food which best inhibits or reduces the intoxicating effect of alcohol, he called for further experimental work. It fell to my lot to carry out this work on behalf of the Central Liquor Control Board. It was characteristic of Lord d'Abernon that he was not content simply to receive the results of this work, but often went to see the experiments on animals and man being made.

Had the Central Liquor Control Board been allowed to continue its work, d'Abernon's success in settling the liquor problem would have been even greater than it was. As soon, however, as Mr. Lloyd George saw that parliamentary agreement could be obtained on some of the Board's recommendations, he jumped in, secured the necessary legislation and dismissed the Board. Even so, its success was enormous, so that in a broadcast in 1931, Lord d'Abernon was able to say that "it had directly or indirectly added 100 millions to the public revenue and had cured the country of nearly two thirds of the evil results of intemperance". Brewers and distillers and public houses continued their lucrative trade, shareholders in these concerns drew the same or larger dividends. Patrons of Bacchus could still get their quota of drinks, although more dilute than formerly, at more restricted hours and greater cost. Most of those directly interested in the trade were happy, and the rest of the country saw less home misery and fewer drunkards in the streets.

It is impossible in this place to write about other activities of Lord d'Abernon, but any one man who could be chairman of the Betting Control Board, of the Medical Research Council, the Industrial Health Research Board, the Lawn Tennis Association, the Thoroughbred Horse Breeders' Association, a trustee of the Tate and the National Galleries, clearly had many attributes of greatness. In the public eye, the most outstanding post held by Lord d'Abernon was his appointment in 1920 as the first British Ambassador to the German Republic, a position he held until 1926. Here again it is impossible to write of his work, but it is no secret that his ambassadorship was very successful and that in the eyes of those Germans who were in a position to know, he was regarded in Germany for several years as its uncrowned king. There was real friendship and trust between d'Abernon and Stresemann in those days, and the death of Stresemann at a crucial moment in international negotiations was always regarded by d'Abernon as one of the major calamities of Anglo-German relations.

After returning from Berlin, d'Abernon wrote a statistical report about conditions in Germany, which aroused great interest, and one result of this was his election to the presidency of the Royal Statistical Society. He was also made chairman of the Royal Commission on Museums and Galleries, and in this capacity rendered substantial services to science. In 1931 he was elected chairman of the Medical Research Council, but, shortly after his appointment, he unfortunately developed the first signs of the illness which incapacitated him, so that for the last five or six years of his life he was unable to participate in public life. It may be said, however, that during the early period of his chairmanship of the Medical Research Council, he broke all precedent by insisting on knowing personally individual workers of the Council, and on discussing with them their problems under investigation. Some of the friendships he formed with scientific men he retained to his death, and he never lost interest in their subject. His belief in the power of science to supply facts and knowledge necessary for the efficiency of the State was implicit, and towards the end of his life he wrote: "given persevering research and the proper use of available knowledge, we can confidently hope that within a generation every individual might be allowed to have the full development of health belonging to his inborn potentiality." Had we a few more men of affairs who, in addition to paying lip service to scientific methods and results, had the same belief in science and the prepared mind to make use of it, Great Britain would be a better place in which to live.

In 1934 Lord d'Abernon was elected to the fellowship of the Royal Society, a distinction he greatly prized.

EDWARD MELLANBY.

Mr. T. E. Barr Smith

By the death of Tom Elder Barr Smith which was recently announced by cable, South Australia has lost one of the best of her citizens and the University of Adelaide a good counsellor and generous friend.

T. E. Barr Smith received his school education at St. Peter's College, Adelaide, whence he proceeded to Trinity Hall, Cambridge. He was the senior member of the firm of Elder Smith & Co., shipowners and wool merchants of Adelaide, with large pastoral interests in South Australia. Being intimately acquainted with both the production and marketing of wool, alive to the bearings of scientific research on the former and trusted by everyone, he played a useful part in the development of Australia's primary industry along sound lines.

Education and culture in South Australia owe much to the public spirit and generosity of members of the firm of Elder Smith & Co. When the University of Adelaide was founded in 1874, Sir Thomas Elder provided one half of the cash endowment, and Robert Barr Smith, Tom's father, endowed the library. Some twenty years later, Sir Thomas Elder presented a further handsome sum to found and endow a chair of music and a Conservatorium. Another partner, Peter Waite, left his fortune to endow a chair of agriculture and a research institute as part of the Department of Agriculture. The Waite Institute at Glen Osmond on the outskirts of the city is well equipped and provided for, and one of the most flourishing research institutes in the British Commonwealth. Yet another member of the firm of Elder Smith, Walter Young, served for many years as treasurer, and the University owes much to his wise guidance, particularly during the difficult years of the world economic crisis at the beginning of last decade, when the financial stability of Australia was shaken.

Tom Barr Smith's gifts to the University of Adelaide were generous and frequent. A vigorous young University must continuously expand its activities, and he contributed handsomely towards many of its developments. His largest single gift was a new home for the library. The Barr Smith Library is a fine separate building with ample provision for expansion. It is convenient, comfortable and comely. It serves as a noble monument to keep green the memory of one of the best friends of the University in the minds of future generations of alumni.

Tom Barr Smith was genuinely interested in science and learning, and found enjoyment in the companionship of those with similar tastes. Many scientific visitors to Australia will remember the charming hospitality extended to them by Mr. and Mrs. Barr Smith at their home at the foot of the Adelaide Hills, and their enjoyment of the company of this kindly, modest and shrewd Australian.

CHARLES MARTIN.

WE regret to announce the following deaths:

Prof. P. Flemming, emeritus professor of ophthalmic medicine and surgery in University College, London, known also for his work in archæology, on December 19.

Capt. T. A. Joyce, O.B.E., formerly deputy keeper in charge of the Sub-Department of Ethnography, British Museum, on January 3, aged sixty-three.

Prof. S. M. G. Ure, assistant professor of chemical engineering in the Imperial College of Science and Engineering, and reader in the University of London, on December 25.

Prof. T. Henry Wilson, formerly King's professor of midwifery in Trinity College, Dublin, and president of the Royal College of Physicians of Ireland during 1926–27, on November 20, aged seventy-eight.

NEWS and VIEWS

The Washington International Pact

WHEN the history of the present times comes to be considered by a future generation, it is probable that the joint declaration signed at Washington on January 1, by the countries arrayed against one or more of the Axis powers, will mark a significant phase in the history of the world. By this document, no fewer than twenty-six nations have voluntarily subscribed to the fundamental principles of the Atlantic Charter signed by President Roosevelt and Mr. Winston Churchill last August. They have asserted their belief in the sanctity of human life, liberty and independence, and the preservation of human rights, justice and religious freedom in all lands. Further, the declaration is open to be adhered to by any other nations contributing to the struggle against the militarism, aggression and oppression represented by Nazism. By this momentous step, the freedom-loving nations have banded themselves together against a common enemy, and little imagination is required to see in it the beginning of the international collaboration which must follow the War if the world is not to be subjected to further upheavals with all the horrors of modern warfare. The free association of nations in the task of ridding the world of Nazi tyranny, and from the medieval suppression of learning and of freedom of thought which have characterized its progress through Europe, is a necessary preliminary to the building of that better 'order' towards which the thoughts of men are turned.

New Year Honours

THE following names of scientific men and others associated with scientific work appeared in the list of New Year Honours :

G.C.B. : Sir Frank Smith, controller of telecommunications equipment, for services to the Ministry of Aircraft Production and to the Ministry of Supply.

Knights : F. C. Cook, chief engineer, Highways, Ministry of War Transport ; Col. J. R. Davidson, lately chief engineer, Metropolitan Water Board ; A. H. R. Fedder, chief engineer, Bristol Aeroplane Co., Ltd. ; H. M. Glover, chief conservator of forests, Punjab ; Prof. Bennett Melvill Jones, professor of aeronautical engineering, Cambridge, for services to aircraft development ; Dr. Cattamanchi R. Reddy, vice-chancellor of Andhra University ; Rao Bahadur Tiruvadi S. Venkataraman, sugar-cane expert, Coimbatore.

C.B. : Col. E. Gold, deputy director, Meteorological Office.

C.M.G. : Major G. St. J. O. Browne, labour adviser to the Secretary for the Colonies ; Prof. H. C. Sinderson, professor of medicine, Royal College of Medicine, Iraq ; A. J. Wakefield, inspector-general of agriculture for the West Indies.

C.I.E. : Sri Krishna, Forest Research Institute, Dehra Dun ; J. C. McDougall, Indian Agricultural Service, Central Provinces and Berar ; J. W. Nicholson, conservator of forests, Orissa.

C.B.E. : Dr. G. C. Anderson, secretary, British Medical Association ; J. M. Crofts, lately secretary, Northern Universities Joint Matriculation Board ; Miss M. Curtis, principal assistant secretary, War Damage Commission, principal designate of Newnam College, Cambridge ; A. C. Inskip, adviser to the Government of India on tanning and leather ndustries ; W. A. Macpherson Walker, adviser to the Government of India on jute supplies ; F. J. Martin, director of agriculture, Sierra Leone ; E. C. Ramsbottom, director of statistics, Ministry of Labour and National Service ; A. P. Rowe, superintendent, Telecommunication Experimental Establishment, Ministry of Aircraft Production ; Prof. S. P. Smith, professor of electrical engineering, Royal Technical College, Glasgow ; A. Wilson, a director of Imperial Chemical Industries (Explosives) Ltd., for services to the Ministry of Supply ; J. F. Wolfenden, lately director of pre-entry training, Air Ministry, headmaster of Uppingham.

O.B.E. : W. Abbott, staff inspector of engineering, Board of Education ; N. Barraclough, deputy chief inspector of mines, India ; W. R. Benzies, superintendent of natives, Bulawayo ; P. H. Carpenter, director, Scientific Department, India Tea Association, Tocklai, Assam ; E. L. P. Foster, chief forest officer, Andamans ; J. H. N. Hobday, chief veterinary officer, Bechuanaland ; G. Mayne Hopkins, divisional forest officer, United Provinces, India ; P. I. Kitchin, principal of Rugby College of Technology and Arts ; G. H. McKenzie, assistant production manager, Imperial Chemical Industries (Explosives) Ltd. ; H. E. Page, superintendent, Cordite Factory, Aravankadu ; P. E. Pollard, principal scientific officer, Air Defence Research and Development Establishment, Ministry of Supply ; N. S. Stevenson, conservator of forests, British Honduras ; J. Thompson, chief inspector of fisheries ; Dr. A. B. Wood, superintending scientist, Mine Design Department, Admiralty.

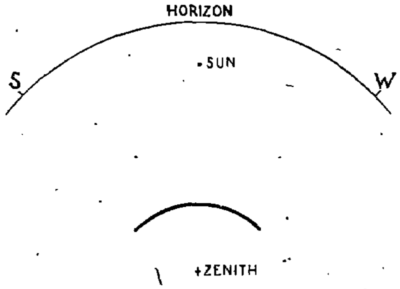
M.B.E. : P. W. Augier, divisional forest officer, Bihar ; J. McC. Black, a prominent botanist in South Australia ; W. E. Butler, factory works manager, Imperial Chemical Industries (Explosives), Ltd. ; J. A. Crosbie, mechanical engineer, Sind ; A. V. Gibberd, agricultural officer, Nigeria ; M. J. McDonald, divisional forest officer, Gorakhpur, United Provinces ; N. P. Mohan, deputy conservator of forests, Punjab ; Miss C. Murray, lately superintendent of domestic science, Glasgow Education Authority ; N. R. Reid, veterinary officer, Tanganyika ; B. N. Sarkar, deputy director of agriculture, Bihar ; J. T. Stapleton, technical officer, Directorate of Technical Production, Ministry of Aircraft Production ; G. V. Trivedi, divisional forest officer, Balaghat, Central Provinces, India ; Major O. H. Wansbrough-Jones, R.E.

University of Sheffield

THE thirty-sixth annual report of the Senate to the Court of Governors of the University of Sheffield for the year ending July 31, 1941, shows that the University had an active year in which academic and national interests had to be nicely balanced. During the year, the Departments of Zoology, Botany and Geography moved into the extensions at Western Bank in preparation for the 1941–42 session, thus releasing much-needed accommodation for the medical sciences and mathematics, and for the library. Fortunately, although no University building escaped damage during heavy air raids, there was little interference with work. The number of full-time students, which was 767 in 1938–39, fell to 667, but it is stated that the figures for the current session show no further decline ; only about a quarter of the students submitted themselves for voluntary medical examination at the beginning of the session. The Department of Engineering was engaged for some time with day and night training of semi-skilled mechanics for armament factories, thus anticipating the Ministry of Labour scheme, and has since turned to the production of munition components. Many members of the staffs of the Departments of the Faculties of Pure Science, Medicine, Engineering and Metallurgy, have carried on research work in connexion with the war effort in addition to their normal duties. The Regional Committee for Education in H.M. Forces, centred in and worked from the University, arranged 702 lectures and talks.

A Brilliant Atmospheric Arc

OPTICAL phenomena appear to have been very prominent in the upper atmosphere over the south-east of England on November 9, 1941. An account of a brilliantly coloured arc has been received from Mr. A. F. Dufton, of the King's Lodge, Hunton Bridge, Herts. Although the colouring is described as fully as brilliant as that of a rainbow, the colours being in the usual sequence with the red outermost, the accompanying sketch, which was sent by Mr. Dufton, shows that the arc was not part of an ordinary rainbow, being parallel with the horizon. The radius of curvature was estimated to subtend about 40°, the sun being estimated to be about 50° from the nearest point of the arc (the middle of the arc). The phenomenon was seen at 4 p.m. B.S.T., and a trace of cirrus cloud was present. On the same day, Mr. L. C. H. Cave, of the Old Rectory, Blechingley, Surrey, as reported in *The Times* of November 24, that he saw a mock sun at Hitchin of exceptional brilliance, also at 4 p.m. B.S.T. This is described as being so bright that it was almost difficult to look directly at it.



West African Forestry during 1940

IT may be asked whether the constant reiteration of the forest policy envisaged for the several Colonies under the Colonial Office produces the results obviously aimed at by the writers of annual forestry reports. The administrative authorities pass these reports and doubtless think that these statements read well and do not commit them to anything; and results in the past have shown this to be true. A forest policy put up by the forestry adviser may be accepted in whole or in part, but ruthlessly countermanded in a few months time for reasons having no connexion with a true appreciation of the value of the forests in the interests of the community. The heads of all three forest services in West Africa, Nigeria, the Gold Coast and Sierra Leone comment in their annual reports on the absence of military duties of a high percentage of their gazetted officers. The Conservator in Sierra Leone has four assistants; yet between them they only put in 18 months work in the department during the year (1940). At the end of the same year twelve officers, about half the Gold Coast forest staff, were on military service; while in Nigeria more than one third of the gazetted staff were on military service or other war-time duties. Yet in each Colony war-time demands are accelerating the exploitation of the forests. It is not therefore surprising that much of the work of a trained forest officer in the introduction of a proper management, such as reservation, including stock mapping preceding exploitation, in sylvicultural work with the object of the perpetuation of the forest estate, and other professional development work, was almost in abeyance during the year in all three Colonies.

It is difficult to regard this position with satisfaction in view of the recent debates in both Houses of Parliament on Colonial matters. For in each the inference was that the Colonial Office is not awaiting the end of the War, but is even now busy considering how the administrative machinery may be best speeded up and shaped so as to enable better conditions of livelihood to be enjoyed by the populations in the future. Where the improvement of agricultural practices is in question, or even education, the results —mistakes or otherwise—may become apparent within a few years. This is not the case with forestry. The postponement and procrastination displayed in the acceptance and adoption of a correct forest policy is almost a commonplace when applied to many of the Colonies; as is a recognition that forests cannot remain in a balancing or stable condition. They are either constantly improving or degrading. The most serious result of the absence of so many officers from the forest departments is the further delay in speeding up the placing of forest areas into the category of reserves when they come under the direct management and care of the forest officer.

Public Health in the United States

ACCORDING to provisional data for 1939 compiled by the Public Health Service of the United State the general mortality in 45 States, the Districts o Columbia, Hawaii and Alaska, was 10·7 per 1,000 inhabitants, as compared with 10·6 in 1938. Infantil mortality was 48 per 1,000 living births, the lowest hitherto recorded. The fall in maternal mortalit continued, being 10 per cent lower than in 193 (4 per cent live births). During the year 1939 n case of cholera or yellow fever was reported, but on case of plague was notified in the State of Utah There were 403,037 cases of measles, or less tha half the number in 1938, and 9,877 cases of smallpox as compared with 14,938 in the previous year At the beginning of the summer of 1939 there was a outbreak of poliomyelitis in the States of the Atlanti coast with a total of 7,339 cases compared with 1,70 in 1938. The incidence of diphtheria, cerebrospina fever, scarlet fever, typhoid and paratyphoid fever was much less than the average for the quinquenniu 1934–38. There was an outbreak of influenza i February 1939 which subsided towards the midd of July, but there was another outbreak in Octobe which lasted until June 1940; in 1939 there wer 275,503 cases notified, or more than double those i 1938 and 40 per cent above the average for th quinquennium 1934–38. 2,996 cases of typhoid fev were notified in 1939 as compared with 2,294 i 1938. The mortality from typhoid, paratypho measles, scarlet fever, diphtheria, encephalitis, meningitis, tuberculosis, malaria, pellagra, affections of t alimentary tract, syphilis, diarrhœa and enteritis in children under two years, and accidents (including motor accidents) were the lowest reported in the last five years. The mortality from pneumonia was very low in 1939, the diminution being more than 33 per cent compared with 1938. The increases in the mortality from cancer, diabetes, cerebral hæmorrhage and heart disease must be attributed principally to the greater age of the population.

Nature of the Long-period Variable Stars

R. M. Scott has an article on the long-period variable stars in the *Telescope* of September–October, which provides a popular description of the type of star of which Mira is a prototype. The spectra of these stars reveal that they are cold enough to contain molecules, and yet sufficiently hot to show the bright lines of hydrogen and ionized metals, and a brief explanation of the probable reason for this follows. Assuming that these stars are pulsating, we can picture a small core about the size of our sun surrounded by an atmosphere extending to a distance comparable with that of the earth from the sun. Viewed from a distance, one of these stars would present the appearance of a luminous fuzzy ball, deep in a hazy murk, and it is easy to imagine flames similar to solar prominences hovering deep in the smoky atmosphere near the luminous core. Then as the star approaches minimum the atmosphere would become darker and more clouded and the core a deeper red, the eruptions practically disappearing. It is possible that these red variables may be a link in the evolutionary chain, great numbers of stars starting their lives as red variables and then outgrowing their adolescent pulsations. On the other hand, red-variable pulsations may represent the palsy of stellar old age, though the former theory is the more popular of the two. At present this type of star presents a problem which can only be solved by much more investigation.

William James (1842–1910)

William James, the well-known psychologist and philosopher, was born in New York on January 11, 1842, the son of the Swedenborgian theologian Henry James and brother of the novelist Henry James. He studied medicine at Harvard, where he qualified in 1869. He never engaged in practice, but after occupying the chairs of anatomy and physiology at Harvard he devoted himself entirely to psychology and philosophy. From 1889 until 1897 he was professor of psychology and from 1897 until 1907 professor of philosophy at his *alma mater*. During his last years he was chiefly occupied by the study of religion and metaphysics. He is perhaps best known for his championship of the doctrine of pragmatism inaugurated by C. S. Peirce of Cambridge, Massachussets, according to which the value of any assertion is tested by its practical bearing upon human interests and purposes. He died on August 27, 1910. His principal publications were "Principles of Psychology" (1890), "Talks to Teachers on Psychology (1899), "Varieties of Religious Experience" (1902), and "Pragmatism" (1907). Numerous honours were conferred upon him at home and abroad, including membership of the National Academies of America, France, Italy, Prussia and Denmark, doctorate of letters at Padua and Durham, doctorate of laws at Harvard, Princeton and Edinburgh, and doctorate of science at Oxford and Geneva.

Association of Special Libraries and Information Bureaux

The sixteenth annual general meeting of the Association of Special Libraries and Information Bureaux was held on December 13, 1941. The chair was taken by the president, Sir Harry Lindsay, director of the Imperial Institute, whose introductory remarks touched on the widening scope of the Association's activities, a subject that was further developed by Mr. E. J. Carter, the honorary secretary, in his review of the year's work. The Association was fortunate enough to come through the winter's air-raids with only minor damage to the office; membership has remained steady and publications continued as usual. New opportunities for service arising from war conditions have been seized, among which was the investigation into the location and supply of scientific and technical periodicals now reaching the country from enemy and enemy-occupied territories, a survey carried out under the auspices of the Royal Society and the Rockefeller Foundation. Further details of the information thus compiled can be obtained on application to the ASLIB Office at 31, Museum Street, London, W.C.1. Other projects for bibliographical co-ordination are being considered.

Medical History of the War

An editorial board, under the chairmanship of the President of the Board of Education and composed of representatives of the Fighting Services, the Ministry of Health, the Department of Health for Scotland, the Committee of Imperial Defence and the Medical Research Council, has been set up by the War Cabinet to direct the preparation of a "Medical History of the War". The Board met recently and discussed the scope and planning of this undertaking, the value of which as a record of medical work during the War and of the War's contribution to medical science, will be appreciated. Sir Arthur MacNalty, until recently chief medical officer of the Ministry of Health, has been appointed editor-in-chief. The collection and classification of material for the "History" has now begun. The Editorial Board would be glad to receive copies of published articles, reports and other information from medical officers of health and medical practitioners which may be of use in assembling material for the medical historians; such data should be communicated to the Editor-in-Chief, Medical History of the War, Room 208, Caxton House West, Tothill Street, London, S.W.1.

Announcements

It is announced by the New York correspondent of *The Times* that the Mount Palomar Observatory, in California, which is to house the 200-in. telescope, will be closed on January 15 and will remain closed for the duration of the War.

Prof. Louis F. Fieser, professor of organic chemistry in Harvard University, has been awarded the Kathleen Berkan Judd one thousand dollar prize of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York City, in recognition of his contributions to cancer research. Prof. Fieser's work in this connexion has dealt chiefly with chemistry and synthesis of carcinogenic compounds.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Lactic Dehydrogenase of Yeast

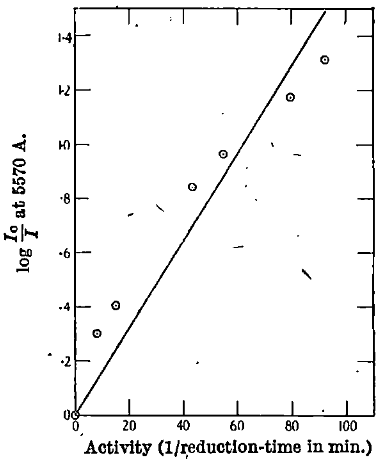
Dehydrogenases are of three types: (1) those which act through coenzymes I or II, (2) flavoproteins, and (3) the 'cytochrome-reducing dehydrogenases', a group of enzymes of unknown chemical nature which have the power of reducing cytochrome *c*. The members of the third group are all insoluble and firmly attached to the solid structure of the tissues, with the exception of the yeast lactic dehydrogenase, first extracted from yeast by Bernheim[1]. This enzyme is, therefore, the only one of the group which can be extensively purified with the view of determining its chemical nature. We have carried out such a purification, and have obtained solutions nearly five thousand times as active as those which Bernheim obtained. The following method was used:

Delft baker's yeast is pressed through an ordinary potato masher and air-dried at room temperature. 3 kgm. dried yeast, mixed with 6 l. tap water, are incubated 5 hr. at 38° for autolysis, then 4·5 l. water are added and the residue centrifuged off and discarded. The liquid (6·3 l.) is mixed with 1 l. of alumina Cγ gel (containing 15 mgm. dry weight per c.c.), which adsorbs much coloured material, including most of the cytochrome *c*. The alumina is centrifuged off and discarded. 140 c.c. 50 per cent sodium lactate are added, the fluid heated to exactly 53° for 7 min. and the large precipitate of denatured protein centrifuged off. The liquid (6·2 l.) is mixed with 3·5 l. calcium phosphate gel (containing 20 mgm. per c.c.), centrifuged and the supernatant fluid discarded. The calcium phosphate is then washed five times, each time with 2·5 l. $M/15$ phosphate buffer *p*H 7·2, by thorough dispersion with a mechanical stirrer and centrifuging. Much protein and coloured material, especially flavin compounds, are thus washed out. The calcium phosphate is then eluted three times at 40° with $M/15$ phosphate *p*H 7·2 containing 9 per cent of ammonium sulphate, using 2·8 l. in all. 10 c.c. 5 per cent sodium lactate is added, the solution filtered and then concentrated to 130 c.c. on the ultra-filter, using "4½ per cent" Schleicher membranes. 31 gm. pure ammonium sulphate are added and the precipitate centrifuged off and discarded. A further 18·5 gm. ammonium sulphate are added, the precipitate centrifuged down and dissolved in water to make 53 c.c. The enzyme is freed from cytochrome *c* by ammonium sulphate fractionation in acid solution as follows: 26 c.c. $M/5$ acetate buffer *p*H 4·8 and 53 c.c. water are added to the above red solution, followed by 37 gm. ammonium sulphate. The precipitate is centrifuged off and discarded. 5 gm. ammonium sulphate are then added, the precipitate centrifuged down and dissolved in water to make 10 c.c.

The enzyme is very unstable in the purer stages. The addition of substrate (lactate) improved the stability, as did a high concentration of ammonium sulphate. But even in saturated ammonium sulphate solution the activity of the purest fractions could only be preserved for 2–3 hr.

The purified fractions of the enzyme have lost the power of reacting with cytochrome *c*, though their power of reducing methylene blue is very high. This effect is apparently due to the removal of some intermediate hydrogen acceptor, which acts[2] between the enzyme and cytochrome *c*.

The solution obtained as described above was quite free from cytochrome *c*, but on the addition of lactate gave the spectrum shown in the graph of a preceding communication[3]. As already stated, this is due to a new cytochrome component and its presence suggests the possibility of its being identical with the enzyme. Although definite proof has not yet been obtained, the following points suggest that this is so. (*a*) The new cytochrome is reduced instantly on the addition of a trace of lactate. (*b*) In different preparations the band at 5570 A. always appears when the enzyme activity reaches a certain value. (*c*) Thereafter the strength of the band and the activity increase *pari passu* as the purification proceeds (see accompanying graph). (*d*) Further evidence is provided by observations on English baker's yeast. The latter cannot be used to prepare the enzyme by the above method, as the enzyme is not liberated by the autolysis, and in order to obtain the enzyme from such yeast a very different method had to be devised. This involved breaking the plasmolysed cells of the fresh yeast by grinding in a ball-mill, warming with toluene, adsorbing on kaolin and eluting with 20 per cent ammonium sulphate, followed by dialysis and adsorption on calcium phosphate as before. When the activity reached the same value as before, the band at 5570 A. again appeared, and in a concentrated fraction obtained in such a way the intensity of the band was approximately that which would be expected from the activity, using the data obtained from the original preparations. No trace of the coenzymes could be detected in the purified preparations by very sensitive tests, and although a trace of flavoprotein was often detectable in solutions obtained by the method described, a slight modification gave active solutions in which no trace of flavin compounds could be detected by the fluorescence test.



While we consider it probable that the cytochrome b_2 is identical with the enzyme, the possibility cannot yet be altogether excluded that it is an intermediary acting between the enzyme and methylene blue or other hydrogen acceptor.

Assuming that the enzyme is identical with cytochrome b_2, the turnover number of the pure enzyme can be calculated from the activity and the amount of cytochrome b_2 present. The figure obtained is

3,100, which can be considered a reasonable value, being in fact identical with the turnover number of crystalline lactic dehydrogenase from muscle[4], though this is no doubt a coincidence, as the two enzymes belong to different groups. The maximum turnover number of cytochrome *c* is 3850[5]. The calculated purity of our final enzyme solutions depends on the assumed molecular weight, but is probably of the order of 10–20 per cent. The Q_{MB} of the pure enzyme would be 30,000–100,000, according to the molecular weight assumed. A calculation from the activity of the Lebedew juice shows that 1 kgm. of yeast contains only a few mgm. of the pure enzyme.

The idea that a cytochrome, or indeed any other hæmatin compound, may act as a dehydrogenase is a new one and may throw light on the nature of other dehydrogenases of the third group.

The work will be reported in greater detail elsewhere.

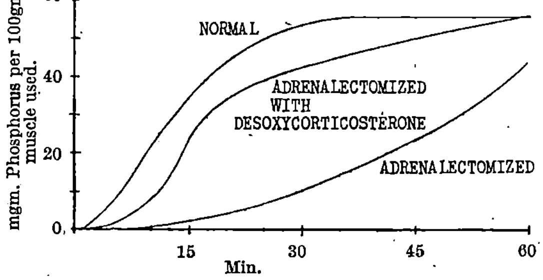
Decrease in Glycogen Phosphorylation in Muscles *in vitro* after Adrenalectomy and Restoration with Desoxycorticosterone

IT has been supposed that a diminution of phosphorylation is the main disturbance after adrenalectomy, and that this is proved by a study of the direct phosphorylation of glycogen by muscle.

If 0·5 gm. of leg muscle of a normal rat is minced and placed in 2 c.c. of a solution of 1 per cent sodium bicarbonate with 1·75 per cent sodium fluoride, then inorganic phosphate is dissolved from the muscle. If 0·25 per cent of glycogen is then added to such a solution, the inorganic phosphoric acid content of the solution decreases and the glycogen is phosphorylated (Bodnár and Tanko, Lohmann, Parnas). The muscles of adrenalectomized rats lose this capacity of phosphorylating glycogen *in vitro*. This was first shown by Schumann (1940), but simultaneously Helve (1940) did not find this difference.

We have studied the time relations of this reaction with the muscles of normal and adrenalectomized rats. Normal rat muscle uses about 54 mgm. phosphorus per 100 gm. of muscle. At 20° C. the reaction ends in 30–60 minutes, and at 37° C. in 10–20 minutes. With muscles of adrenalectomized rats, the reaction is much slower and within the physiological time limit it is strikingly decreased. In thirty-seven adrenalectomized rats only about 11 mgm. phosphorus was used up after thirty minutes. The reaction then slowly continues and may, after three hours, give values equal to those found in normal muscle after thirty minutes at 20° C. or after twenty minutes at 37° C. This explains why Helve, who kept the muscle at 37° C. for 3½ hours, did not observe a decrease in phosphorylation.



PHOSPHORYLATION OF GLYCOGEN BY RAT MUSCLES *in vitro* AT 20° C.

The accompanying figure shows the time relations of the reaction based on mean values of experiments on normal and adrenalectomized rats' muscle at 20° C. The decrease in phosphorylation in the latter is obvious. It is already found in animals which are still only slightly adynamic. Only animals which were still in good condition were used for these analyses. Generally speaking the more time had elapsed after the adrenalectomy, the less phosphorylation occurred. Table 1 gives some values at 20° C. after sixty minutes and at 37° C. after twenty minutes for comparison.

Table 1.

MGM. PHOSPHORUS PER 100 GM. MUSCLE USED.

Normal rat muscle (21 animals)	45–64 (mean 54)
On 4th day after adrenalectomy	26, 22
,, 5th ,, ,, ,, ...	36, 36, 22, 40, 22
,, 6th ,, ,, ,, ...	28, 26, 20, 26
,, 7th ,, ,, ,, ...	8, 4, 39, 15, 8
,, 8th ,, ,, ,, ...	6, 20, 16, 18

(Each figure refers to a separate rat)

We then tried to restore phosphorylation by adding desoxycorticosterone acetate to these muscles *in vitro*. A 1 per cent solution in 66 per cent propandiol-water was made and 0·1 c.c. added to the system described of 0·5 gm. muscle with glycogen. Desoxycorticosterone restored the decreased rate of phosphorylation with muscle of adrenalectomized rats to the normal rate in all cases (muscles of twelve animals at 20° C., and four at 37° C.); it did not increase the rate of glycogen phosphorylation of normal rat muscle where it was already optimal (three experiments). As a control the action of other steroid hormones, œstradiol and similarly of testosterone, was compared. Neither of these hormones had any action whatever on the rate of phosphorylation, with normal or adrenalectomized rats' muscle.

Table 2.

MGM. PHOSPHORUS PER 100 GM. MUSCLE USED.

	Desoxycorticosterone (Without)	Desoxycorticosterone (With)
On 4th day after adrenalectomy	20	36
,, ,, ,, ,, ,, ...	42	54
,, 5th ,, ,, ,, ...	36	64
,, ,, ,, ,, ,, ...	48	68
,, 6th ,, ,, ,, ...	26	40
,, ,, ,, ,, ,, ...	28	52
,, 7th ,, ,, ,, ...	39	62
,, ,, ,, ,, ,, ...	8	30
,, 8th ,, ,, ,, ...	10	19
,, ,, ,, ,, ,, ...	18	30

These experiments seem to give a proof that phosphorylation disturbances are the main factor in adreno-cortical insufficiency. It must be emphasized that the restoration took place not in the animal but *in vitro*. A detailed report will be given in *Helvetica Chimica Acta*.

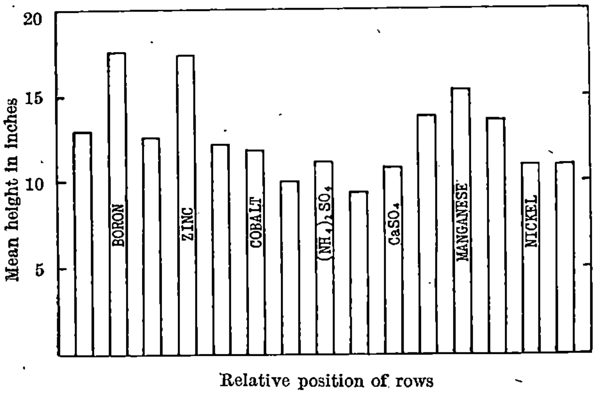
Trace-elements and 'Potato-sickness'

IT is well known that infestation with the potato strain of the eelworm *Heterodera schachtii* Schmidt is not the sole cause of the disease known as 'potato-sickness'. It occurred to me that some nutritional deficiency might be a contributory factor. The disease nearly always occurs on land on which potatoes have been grown continuously for a number of years, and it seemed possible that this might well lead to the soil being exhausted of certain vital elements required by the plant in small quantities and normally neglected in manurial treatments and soil analyses. A small-scale attempt to test this hypothesis was made during 1941 and some promising results obtained. These, however, were of a preliminary nature and a more extensive investigation is planned for the future. A detailed account of this year's work is now in preparation; in the meantime it was thought advisable to publish the following note in the hope that it might be of use to other workers who may be interested in the problem.



MEAN HEIGHTS OF THE GROUPS OF FIVE PLANTS IN THE MOST DILUTE ZONE SHOWN IN THEIR RELATIVE POSITION IN THE PLOT. UNTREATED ROWS ALTERNATE WITH TREATED ROWS. THE ROW MARKED '$CaSO_4$' RECEIVED A HEAVY DRESSING OF THIS SUBSTANCE IN POWDER FORM IN THE DRILL AT THE TIME OF PLANTING. SIX OTHER ROWS OF PLANTS IN A SEPARATE BLOCK ARE NOT SHOWN IN THIS FIGURE.

A small plot of land, badly infested with *Heterodera schachtii*, was planted with a series of rows of potatoes, each row containing fifteen plants. Some of the rows were watered, at weekly intervals, with dilute solutions each containing a single salt of certain of the trace-elements. The strength of the solution was halved for each successive group of five plants in the row. Three strengths of the various solutions were thus used, and of these, the solution applied to the second five of the fifteen plants was of the same strength as that contained in the solutions used by Arnon in his work on the effect of trace-elements on the growth of lettuce and asparagus seedlings[1]. Treated and untreated rows alternated throughout most of the plot, so that there was, in general, an untreated row on each side of a treated row. Certain of the rows were treated with ammonium salts of similar dilution to act as general controls and also to control any possible effects of the anions of the salts of the various trace-elements used.

The heights of all the plants were measured when flowering began, when it was noticed that all the plants were at the same stage of maturity. The crop was lifted when the last of the tops had died down, and the tubers of each plant weighed.

Weight of crop and height of plant were in general agreement.

The mean height of each group of five plants in the rows varied with the dilution of the solution used, the plants being considerably taller in the zone to which the strongest solutions had been applied, and shortest where the most dilute solutions had been used. The most striking *differences* between treated and untreated plants were shown, however, in the latter zone. For example, the mean height of the plants treated with the most dilute solution of zinc sulphate was 40 per cent greater than the mean height of the untreated plants on each side of them. A similar difference was also found in the case of boric acid, and a smaller, but quite marked, difference in the case of manganese chloride. Yet these treated plants had received extremely minute amounts of the trace-element. For example, *throughout the whole season*, the total quantity of boron supplied to each of the plants treated with boric acid was about 0·5 mgm., while the total quantity of zinc supplied to each plant treated with zinc sulphate was about 0·05 mgm. It is certain that the increases in height were not due to the water supplied, for the differences are just as marked when the treated plants are compared with plants treated with water alone or with those treated with the dilute solutions of the various ammonium salts. Some of these points are clearly shown in the accompanying figure.

The plants treated with the more concentrated solutions showed the same general effects, save that the percentage differences between treated and untreated plants were not so large. It is probable that, under the conditions of the experiment, the treatments spread to the adjacent untreated rows and that this tendency was greater the stronger the solution used. It was also evident that the plot was by no means homogeneous in degree of infestation with eelworm, but although this would help to explain the fact that the tallest plants were all found in the zone to which the strongest solutions had been supplied, it cannot account for the marked differences between the treated plants already referred to and those immediately adjacent to them.

Cotton Seed Disinfection in War-time

IN the Sudan cotton seed has to be treated with a mercurial dust for the control of blackarm (*Bacterium malvacearum* E.F.S.), present on the seed as an external infection[1,2].

On the outbreak of war the possibility arose of there being a shortage of mercurial dusts in the country. It therefore became expedient to provide an alternative method for the disinfection of cotton seed in the event of such an emergency.

B. malvacearum in cotton debris is destroyed when cotton fields are flooded for a period of four days with irrigation water[3]. The disappearance of the organism is attributed to the action of a bacteriophage. Experiments were performed to discover whether *B. malvacearum* on cotton seed could be destroyed in a similar manner.

It was found that after steeping cotton seed for forty-eight hours in four times its own weight of irrigation water practically all traces of external infection by *B. malvacearum* had disappeared. In small-scale plant-house experiments on seed which when untreated gave 14 per cent infected plants, complete control of the organism was obtained. A larger field experiment, using infected seed from the same source, gave 0·26 per cent infected plants after the steeping treatment, and complete control after using a mercurial dust, Abavit B.

Germination of the seed is depressed by the steeping treatment, but not seriously so. In a field experiment unsteeped seed gave 79 per cent germination, and steeped 72 per cent. The steeped seed had been dried and stored for a short period after treatment. If the steeped seed cannot be sown wet immediately, and has to be dried and stored, the drying process must be rapid and thorough. Otherwise the seed will promptly germinate.

From laboratory experiments it would appear that the organism disappears from the surface of the seed during steeping, not through the activity of a bacteriophage, but through exposure to anaerobic conditions. These conditions are the result of bacterial activity, and oxygen absorption by the germinating seeds. The growth of *B. malvacearum* in culture is closely conditioned by the amount of oxygen present.

Scattering of Neutrons in Deuterium

USING the neutrons released in the beryllium-deuterium nuclear reaction, we have investigated the scattering of medium fast neutrons in deuterium gas. The bombarding deuteron beam of 4 micro-amperes was accelerated with a peak voltage of 600 kilovolts in a short ion path tube[1], using the 1 Mv. cascade transformer at the California Institute of Technology. The neutrons emitted in a direction perpendicular to the bombarding deuteron beam traversed a brass pressure ionization chamber filled with deuterium gas at 7 atmospheres. The energy of the recoil deuteron was measured by a linear amplifier which fed a mechanical oscillograph, the pulses being recorded on a moving film. Calibration pulses were registered on the same film with a thyratron pulse generator and a standard condenser. More than 4,000 tracks were measured, the longest pulse track corresponding to an energy of 2 Mev. The curve giving the distribution in energy is shown in Fig. 1.

The maximum at 1·2 Mev. may correspond to the peak energy of the low-energy group of neutrons[2] released in the beryllium-deuterium reaction. The more prominent maximum at 0·7 Mev., presumably, is due to an anomaly in the neutron-deuteron interaction. It may be associated with the "Ramsauer effect" deduced[3] by Massey and Mohr on the basis of a potential interaction of range $4\cdot5 \times 10^{-13}$ cm. Assuming the approximate validity of the equation deduced by Baldinger *et al.*[4] for the distribution in energy of the primary neutrons in terms of the energy distribution of the recoil nuclei, the curve in Fig. 2 has been plotted with the cross-section values given by Massey and Mohr (*loc. cit.*). The graph indicates a wide spread of energy in the neutron beam, which gets scattered in the gas contained in the ionization chamber. The anomaly at 0·7 Mev. may also be associated with the critical wave-length $\lambda_{cr} = 5\cdot4 \times 10^{-13}$ cm. deduced by Bethe[5] on the basis of a continuum theory of the compound nucleus. As recently stressed by Massey and Buckingham[6], further experimental data may be needed to establish the nature of fundamental nuclear forces.

Anomalous Viscosity of Lubricating Oil at High Velocity Gradients

AN analysis of data recently put forward by Spiers[1], on the flow of oil through engine bearings, shows that the results cannot be reconciled with the usual hypothesis of a viscosity coefficient independent of the velocity gradient. The data indicate that at velocity gradients between 10^4 and 10^6 sec.$^{-1}$, the viscosity coefficient falls down to a small fraction of its normal value. This effect is in agreement with experiments carried out by me in 1937[2]. It is presumably due to orientation under shear, an effect well known for particles of extreme anisometry such as those of cellulose and tobacco mosaic virus.

The analysis of Spiers's data will be published shortly. Experimental work on the problem is in hand.

RESEARCH ITEMS

Blackening of Golgi Bodies by Osmium Tetroxide and Silver Nitrate

The problem of the blackening of the Golgi apparatus in various silver and osmic techniques is an old and still unsolved one. Among recent investigations those of P. B. v. Weel and E. Ries are interesting. In a recent communication to the Editors, they claim that there is a Golgi complex containing certain granules which they call "lipochondria", which at some stages produce osmiophilic substances, and are associated with the fatty Golgi substance, which always reduces osmium tetroxide, and has certain adsorptive capacities. Weel notes that after feeding a starved frog (in the cells of the intestine of which a clearly marked reticular Golgi apparatus is present) on peptone and glucose, the reticulum disappears, and is rebuilt again at the end of the resorptive process. But with feeding on fructose, no alteration of the reticulum was noted. Weel insists that the Golgi substance contains fatty materials which are used and consumed by the cell in certain periods of activity. The results of Weel and Ries are sharply at variance with those of G. Chr. Hirsch, who believes that the blackening is due to an adsorption of reduced osmium, silver or iron, and not to any chemical action. While Weel's view, that the osmium tetroxide reaction is a chemical one with lipins existing in the Golgi apparatus, will meet with a considerable body of support, the presence of "lipochondria" seems more doubtful. The papers of Weel and Ries will be found in the *Z. Zellforsch.* and the *Z. vergl. Physiol.* of 1936–1939.

Salmon of the Owenduff (Ballycroy) River

A. W. E. J. Went, of the Department of Agriculture, Fisheries Branch, Dublin, (*Proc. Roy. Irish Acad.*, **47**, Sect. B., No. 6; 1941) has investigated the fishes in this river—a good one for small salmon and sea-trout. The records for the most part depend on scales from rod-caught fish, but give a fairly accurate impression of the stocks of salmon. The bed of parts of the main river and its tributaries which are frequented by salmon and trout consists mainly of gravel, and good spawning facilities are available. The material for the research consisted of more than a thousand sets of scales and data taken from the rod-fisheries of the Owenduff River during the fishing seasons of 1930–1939 inclusive, and 106 similar sets from the net fishery in the estuary of the river in 1938, together with some data from the main tributaries. Owenduff is essentially a small salmon river and the bulk of the fish have spent two years or less feeding in the sea. Of the maiden fish 94 per cent migrated as two-year old smolts and 5·5 per cent as three-year old smolts. Grilse and small spring fish formed 75·8 of the total catch. Previously spawned fish amounted to 4·9 per cent of the total number. The growth of salmon and sea-trout up to the end of the second year in the sea in the two- and three-year smolt classes are compared. The growth-rate of the salmon in fresh water is considerably less than that of the sea-trout. On the other hand, in the sea the growth-rate of the salmon is very much greater than that of the sea-trout. "Although the sea-trout start life in the sea with an initial advantage in length of over 2 inches, by the end of the first winter in the sea the salmon are on an average about 7 inches longer than the sea-trout. This advantage is more than maintained in the second year in the sea."

Microlepidoptera of Ireland

The study of these small moths has been comparatively neglected in Ireland, and generally it is the larger species of the Microlepidoptera that are best known. It appears that the Tortricidæ and Lampronidæ are the best-worked families, and the most neglected are the minute Nepticulidæ. B. P. Beirne has published an up-to-date list of all the species so far known or believed to occur in Ireland (*Proc. Roy. Irish Acad.*, **47**, Sect. B, No. 4). He records 709 species or 54 per cent of the British Microlepidoptera. Of these, 105 species are bracketed as incorrect or doubtful, thus leaving 46 per cent definitely recorded. The classification followed is that of Meyrick, which has been corrected and brought up to date. In describing the distribution of each species, the county-divisions of Praeger, as used in his "Irish Topographical Botany", are followed. In a country that has been so little explored for these insects remarks on the abundance or otherwise of a species are usually not very reliable. It appears that the best-worked county is Dublin, and along with Wicklow and Kerry these three counties are the only ones explored for the smaller species. This carefully prepared list will prove of great assistance to future collectors and observers, who will also find the bibliography at the end very helpful.

Transmission of Monosomics

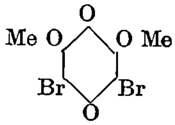
W. H. Greenleaf (*Proc. Nat. Acad. Sci.*, **27**, 427–430; 1941) has analysed the transmission of *n*-1 gametes through the ovule of the monosomic-*P* of *Nicotiana tabacum.* Although a ratio of 3 monosomics to 1 normal plant is expected, only 4 per cent monosomic–*P*, are found. There is no Renner effect; every embryo sac is formed from the megaspore at the chalazal end. There is, however, a reduction in the number of seeds in a monosomic, and the author shows that the embryo-sacs arising from *n*-1 megaspores are much delayed in development as compared with normal. He suggests that delayed pollination might increase the proportion of monosomics in the progeny.

Phosphorus Trifluoride and Oxyfluoride

The reactions between phosphorus pentoxide and simple fluorides and chlorides and with fluorapatite have been studied by G. Tarbutton, E. P. Egan and S. G. Frary (*J. Amer. Chem. Soc.*, **63**, 1782; 1941) and the physical properties of PF_3 and POF_3 have been re-examined. The melting and boiling points found are: PF_3, m.pt. −151·5°, b.p. −101·8; POF_3, m.p. −39·1° at 785 mm. (it sublimes at −39·5°), b.p. −39·7°. The vapour pressure curves were determined and the latent heats calculated. A small amount of difluophosphoric acid HPO_2F_2 (b.p. 108°–111°) was isolated; no previous record of this compound could be found.

Hexamethoxybenzene

In the course of some experiments on derivatives of pentahydroxybenzene, hexamethoxybenzene has been prepared by Sir Robert Robinson and C. Vasey (*J. Chem. Soc.*, 660; 1941). A solution of tetramethoxydiacetoxybenzene in methyl alcohol by hydrolysis and methylation gave hexamethoxybenzene, white needles, m.pt. 81°, b.pt. *ca.* 278°, readily soluble in common organic solvents and moderately readily soluble in water; it can be recrystallized from hot water. The starting substance for the preparation of the tetramethoxy compound was dibromodimethoxy-*p*-benzoquinone:



This was converted by sodium methoxide in methyl alcohol into tetramethoxy-*p*-benzoquinone, and by the action of zinc dust in acetic acid-sodium acetate solution the tetramethoxydiacetoxy compound was obtained. Hexahydroxybenzene is also formed by another process described by W. Baker (*J. Chem. Soc.*, 663; 1941).

Steady Flow of a Viscous Fluid through a Leaky Tube

The classical work of Poiseuille on the steady flow of a viscous liquid through straight tubes of uniform circular section and with impervious walls is not directly applicable to conditions arising in biological problems. Here a similar flow occurs through tubes with membranous walls such as the fine capillaries through the walls of which nutritious fluids get from the blood to working (for example, muscle) cells. F. J. Turton (*Phil. Mag.*, 32, 457; 1941) gives a theoretical treatment of this type of problem applicable to data supplied from the Cambridge Biochemical Laboratory by J. F. Danielli. The investigation shows that with leaky walls the pressure gradient may approximate closely to the constancy found with non-leaky tubes, but for certain conditions known to exist in practice, the mathematical results show considerable departure from constant pressure gradient. At the end of the paper the author offers to help any biologist wishing to use the mathematical results.

Solutions of Wave Equations

Prof. E. Schrödinger, now at the Dublin Institute of Advanced Studies, invites the collaboration of mathematicians in the detailed investigation of certain new types of wave equation. He points out (*Proc. Roy. Irish Acad.*, 47, 1; 1941) that a decisive advance in quantum theory was made in 1934 by the hypothesis of E. Fermi. This asserts that just as Maxwellian waves are descriptive of the motion of light-quanta, but responsible for the forces between electrically charged particles, so the wave fields of de Broglie-Schrödinger-Dirac are descriptive of electrons but responsible for a new kind of forces between heavy particles. The mathematical expression of this leads to wave equations of a new type, and it is very desirable that the solutions of these equations should be fully investigated. A method which seems likely to be very useful is that of taking mean values over a sphere. This method reduces the number of independent variables from four to two. There is also a much more general method which is applicable to the "enlarged wave equation" of any conservative system, but it is not clear whether, in practice, this is as useful as what appear to be more special devices.

Magnitudes and Colours of Northern Stars

The measurement of stellar brightness and colour depends so much on instrumental and atmospheric conditions that photometric catalogues prepared at various observatories are apt to exhibit large discrepancies. The establishment by the International Astronomical Union, twenty years ago, of the North Polar Sequence of standard stars was not altogether successful in removing these difficulties, mainly because the standards were too few, too bright, and too scattered. The obvious remedy was to increase the number of standards. Nearly ten years work to this end at the Mt. Wilson Observatory has now culminated in the issue of a Catalogue (Carnegie Institution of Washington, Publication 532; 1941) of magnitudes and colours for 2,271 stars north of declination +80°. Work on the new catalogue began by a systematic intercomparison of nine well-known polar catalogues; the provisional magnitudes so deduced prepared the way for the reduction of the more recent photographic observations (more than a hundred plates) on which the catalogue chiefly depends. These plates were taken with the 5-inch Ross camera at Mt. Wilson, and were measured in thermo-electric photometers. The limiting magnitude adopted was that of the B.D. Catalogue, roughly 11·0 photovisual. The magnitudes catalogued, photographic and photovisual, are given to two decimal places, and are weighted means of the new data and the older catalogue values, though the new values are also given separately. The probable error of a catalogue entry is about ±0·012 mag. for a photographic, and ±0·015 mag. for a photovisual value. These definitive magnitudes seem likely to supersede the old standards at once; and the scope of the catalogue is such that they may have an even longer life than the values they displace.

Polarization of the Corona

G. W. Allen has published a paper (*Mon. Not. Roy. Astro. Soc.*, 101, 5; 1941) which contains the polarization observations made on the solar corona by the Australian Eclipse Expedition to South Africa on October 1, 1940. The chief object of the investigation was to determine to what extent the polarization of the corona varied with colour. The camera was fitted with a 6-inch Dallmeyer lens of focal length 36 inches. It was fed from an 8-inch cœlostat with silvered mirror and gramophone motor drive. About an inch in front of the plate a 2½-inch disk of 'Polaroid' was placed in such a way that it could be rotated through 90°, and it was oriented to rotate from a polar to an equatorial direction. Interchangeable blue and red filters were mounted between the plate and the 'Polaroid' and two exposures were made on each plate, one with the 'Polaroid' oriented in a polar direction and the other with equatorial 'Polaroid'. One great difficulty in corona photometry arises from the correction for fogging by extraneous light, and at great distances from the sun on the long exposures this extraneous light was much brighter than the corona. The calibration of the photographic plates was effected by the use of a platinum step wedge placed in contact with the plate, and exposure was made inside the camera with the same colour filters, 'Polaroid' and plates as were used for the eclipse. A full description is given of the measurements of the photographs with the Radcliffe Observatory, Pretoria, photo-electric microphotometer, of corrections which were made owing to the incompleteness of the polarization of the 'Polaroids', etc. It was found that the polarization of the corona was practically independent of colour from 4600 A. to 6250 A. and also that it was almost independent of limb distance from 7′ to 40′. The degree of polarization was 41 per cent for red and 43 per cent for blue light.

HETEROTHALLY AS AN OUT-BREEDING MECHANISM IN FUNGI

By DR. K. MATHER

John Innes Horticultural Institution

ALL organisms are dependent on a supply of heritable variation for future adaptive changes; but the presence of free variation means that some members of the population show a poor adaptation to existing circumstances. The balance between present and future adaptation is thus conditioned by the amount of heritable variation which the population can maintain. This, in its turn, depends on the system of breeding or mating in force in the species. Where close inbreeding is in force the individuals tend towards a high degree of homozygosity. Heritable variation is then reduced to a low level, with the result that present adaptation is good but the prospect of future adaptation to changed circumstances poor. When, on the other hand, outbreeding is the rule, great genetical heterogeneity is maintained and in consequence the chances of good future adaptation are improved at the expense of present fitness[1]. In this way genes which control or affect the breeding system of a species have a profound effect on its genetical structure and evolutionary history. They have an adaptive value and will be subject to evolutionary changes.

Many genetically controlled breeding systems have been recognized, and some partly analysed, in the higher plants. Sex separation, incompatibility and heterostyly are now well known as outbreeding systems which depend for their action on genetical diversity in the population. In each case the action of the mechanism is by the reduction of effective mating between genetically like zygotes, while genetically unlike individuals intercross with relative freedom. In the extreme, and most common, case this reduction is complete, though in other cases it may only be partial. The extent of the reduction is itself subject to further genetical control[2]. Since male and female gametes are always distinct haploid individuals, the achievement of wide outbreeding is ensured by the complete prevention of fusion between gametes from the same zygote. All three of the mechanisms mentioned render this possible.

Though showing the same genetic organization as Angiosperms, the fungi, and indeed nearly all lower plants, may be expected to present somewhat different types of breeding system for two chief reasons. In the first place the mating behaviour is a property of the haploid phase in the life-cycle, unlike the situation in the higher forms where the diploid zygote plays such a predominant part. The genes determining the breeding system in fungi must act solely in the haploid, after it has become freed from the influence of the parent zygote. Secondly, a given haploid individual may produce both male and female gametes, or, amounting to the same thing, gametic differentiation may be lacking, in contradistinction to the higher plants where the haploid phase is almost non-existent except in the form of the individual gamete. In view of these differences it is very instructive to consider the type of genetically controlled outbreeding system which might be operative in lower plants, and Buller's recent review of heterothally in fungi[3] provides a very suitable opportunity.

What kind of breeding system, involving genetical diversity, might be expected *a priori* in fungi?

The first essential of any outbreeding system in a species with an independent haploid phase is the prevention of fusion between two gametes produced by a single haploid individual. (It may be noted in passing that this occurrence would lead to a more rigorous inbreeding than is ever possible in a species having a predominant diploid phase, as such self-mating gives immediate homozygosis.) Assuming that the same broad possibilities of cell behaviour exist here as in the Angiosperms, self-mating of a haploid may be prevented in either of two ways. The male and female gametes, if distinct, may be isolated on different haploids or an incompatibility gene may operate in such a way that only haploids carrying unlike allelomorphs can mate. Where gametic differentiation is not present the former possibility is ruled out; but in any event the two systems have a similar genetical basis, for each depends on the production of two (or, in the second case, possibly more) genetically distinct haploids, the allelomorphs determining the two groups acting so as to prevent mating of like types.

Whether the action is one by which allelomorph A_1 gives a haploid with male gametes and A_2 one with female gametes, or whether the action of A_1 and A_2 is of the physiologically unanalysed type known in the higher plants by the name of incompatibility, is genetically immaterial. In either event the matings $A_1 \times A_1$ and $A_2 \times A_2$ are impossible and self-mating of a single haploid is ruled out. Prevention of self-mating in its simplest form requires only two allelomorphs A_1 and A_2. The existence, possible with an incompatibility system, though not with sex separation, of more than two types of haploid does, however, have an advantage over the two-group system when we turn to the next aspect of inbreeding prevention, namely, the control of mating between haploids having a recent common ancestry.

Even if self-mating is prevented, a considerable measure of inbreeding is possible provided that haploids deriving from the same diploid zygote, where, it should be remembered, the all-important recombination occurs, can mate as freely, or more freely, *inter se* than they can with haploids descended from other zygotes. Inbreeding at this level cannot be prevented or even reduced by any system of incompatibility or sex-separating genes consisting solely of allelomorphic pairs. Where a single allelomorphic pair exists all the zygotes must be A_1A_2 and will give A_1 and A_2 haploids. Furthermore, all the zygotes will give equal proportion of A_1 and A_2 haploids; so in any population the ratio which the numbers of A_1 haploids deriving from a given zygote bears to the number of A_1's from other zygotes will on the average be the same as the ratio of the A_2 haploids contributed by these various zygotes. Hence an A_2 gamete will find possible mates from different zygotes in the proportions of the contributions of any kind of spore by those zygotes to the population. The same will be true of the mating choice open to A_1 haploids and so the relative rate of mating between sister haploids from the same zygote is independent of the existence of the two allelomorphs, A_1 and A_2.

Thus all that this pair of allelomorphs does, other than to prevent self-mating, is to halve the number of possible mates for a given haploid individual in the population. It can mate with half its sisters, that is, with the A_2's if it be A_1, or A_1's if it be A_2, just as it can mate with half the haploids from any other zygote.

Two elaborations of this simple system are possible *a priori*, one of which will decrease the frequency of mating between sister haploids and the other of which increases the frequency of mating between non-sisters. The first one is the introduction of a second independent locus B, such that $B_1 \times B_1$ and $B_2 \times B_2$ are impossible matings while $B_1 \times B_2$ is possible. This new gene has, in fact, just the same action as the gene A. All zygotes must be $A_1A_2B_1B_2$ and will produce four types of daughter haploid, A_1B_1, A_1B_2, A_2B_1, A_2B_2. Only two matings are possible between the four, namely, $A_1B_1 \times A_2B_2$ and $A_1B_2 \times A_2B_1$, all the others being prevented either by gene A or by gene B, or, of course, by both. Self-mating is, obviously, also impossible. Any given haploid can mate with only one of the four types, so that only one quarter of the possible combinations in pairs are fertile in the sense that they can give progeny. This compares with the half given by a single gene. When a third member, C, is introduced the freedom of mating is reduced to one eighth.

This type of elaboration certainly reduces the chance of a successful mating between haploids from the same zygote, but, as all zygotes must be $A_1A_2B_1B_2$, it equally reduces the chance of successful mating between haploids from different zygotes. The latter may, however, be increased by the second elaboration. So far in the argument each gene has comprised two allelomorphs, but if a multiple allelomorphic series exists at each locus the freedom of non-sister mating is increased. Suppose that locus A has three allelomorphs, A_1,A_2 and A_3. Three types of zygote will occur, namely A_1A_2, A_1A_3 and A_2A_3. A haploid can mate with only half its sisters from the same zygote, but it can mate with more than half its non-sisters ; for one type of zygote, and, it must be noticed, the most unlike and hence the most distantly related, type of zygote, gives daughter haploids with all of which the first haploid is fertile as it differs genetically from them all. When the three types of zygote are equally frequent the non-sister pairs can mate in 2/3 of cases as compared with the sister mating figure of 1/2. When there are four allelomorphs still more types of zygote are possible and non-sister mating is again increased to 3/4. Non-sister mating increases as the number of allelomorphs increases, but sister mating remains at 1/2.

This increase in the freedom of non-sister mating may be combined with decreased sister mating if several genes each of several allelomorphs are in operation. With two genes each of three allelomorphs, that is, A_1 A_2 A_3 and B_1 B_2 B_3, all allelomorphs being equally frequent in the population, sister mating occurs in 1/4 of cases and non-sister mating in 4/9, giving a non-sister : sister ratio of 16 : 9. This compares with 4 : 3 when only one gene of three allelomorphs is in control. With two genes of four allelomorphs the ratio is 9 : 4, that is, the rate of outbreeding as measured by relative frequency of non-sister and sister mating is once again increased. Thus by a combination of several unlinked incompatibility loci each with several allelomorphs a high rate of outbreeding can be achieved. It may be noted, however, that mating between haploids from the same zygote can never be completely prevented in the way that any of the three breeding systems mentioned earlier for higher plants completely prevents it. To do this would require that the diploid phase could implant in all its daughter haploids some single incompatability character which overrode their own constitution and determined their behaviour in mating. This is in fact done by higher plants [2,4], but, perhaps as a result of the lower degree of organization of diploid life, has not, so far as I know, been encountered in any lower plant.

When Buller's review is examined in the light of this system, built up from principles developed to explain the behaviour of Angiosperms, it will be seen that all levels of elaboration, and hence of controlled outbreeding, are found.

In forms like *Coprinus lagopus* and *Schizophyllum commune* the complete system involving multiple allelomorphic series at more than one locus is found. It may be remarked that, when viewed in this new light, the true nature of the so-called sexual races of these fungi is very clear. They are no more races than are any pair of fully cross-compatible plants in species like the sweet cherry and the red clover. The different diploid fruit bodies, which, by being fully inter-fertile, gave rise to the idea of sexual races, are seen merely to have different allelomorphs at each of the incompatibility loci which, taken together, control the breeding system. The next generation from a cross between such diploids would contain sister zygotes which, on this criterion, could equally well be classed as belonging to different sexual races. It can be predicted that a suitable search should bring to light wild fruit bodies which have one allelomorph in common at either or both of the loci. These would exhibit an inter-fertility which, though incomplete, would be greater than that observed when haploids from the same fruit body are interbred. Such a find would complete the evidence for the artificiality of the sexual race concept.

There are also examples of intermediate elaboration where only one incompatibility locus is found. Though apparently less fully investigated from the point of view of multiple allelomorph detection, at least one of these species, *Coprinus rostrupianus*[5] has such a series. No doubt other cases could be found without much difficulty.

The last stage of control is shown by fungi such as the heterothallic Mucor species where a single gene of two allelomorphs prevents self-mating but where the degree of outbreeding beyond this point is a matter of chance. Sometimes this mechanism appears to survive as a relic after another form of control has been superimposed. Such a case is provided by certain Ustilago sp., for example, *U. hordei*[6] where the four products of meiosis unite in pairs in the single-celled stage, at which self-mating would appear to be ruled out in any case. An inbreeding system has been developed by the retention of the four spores in such a way that the most likely pairings are those between unlike products of the same meiosis, that is, of the same diploid zygote. It would appear that this is an example of adaptation to secure an intermediate degree of inbreeding similar to those obtaining in higher plants like Triticum and Pisum. In these higher plants, too, the present inbreeding mechanism has been superimposed on an outbreeding system, the relics of which may still be observed.

Lastly, there are the cases where heterothally is not found and self-mating may occur. Such homothallic species are capable of rigorous inbreeding, but this may be controlled at an intermediate level by a display of incomplete or partial heterothally. When this happens a haploid is capable of self-mating, that is, of homothallic behaviour, but will in particular circumstances show a preference for mating with other individuals, that is, show heterothallic behaviour. It is as though the individual possessed partially effective heterothally genes. In this way a balanced inbreeding-outbreeding system can be maintained.

It is also possible that such behaviour exists as a stage in the transit between full homothally and full heterothally. In *Primula sinensis*[2] and Petunia sp.[7] the efficiency of the key outbreeding genes is probably controlled by modifying polygenes. The main genes for heterostyly in the one case and for incompatibility in the other may then give either increased or decreased outbreeding by selection of the polygenic complex. Though not yet proved, it seems likely that selection could even reduce the efficiency of the outbreeding genes to zero, that is, completely to remove their power of affecting the breeding system. If this is so, it is easy to see that polygenic selection could lead to the gradual development of an adaptive breeding mechanism. The intermediates between homo- and heterothallic behaviour are susceptible to a similar interpretation and this could be tested by suitable selection experiments. The question of how a + and a – nucleus can occur in different parts of the same homothallic haploid then resolves itself, as, on this view of polygenic modification, the nuclei, though capable of developing heterothallic behaviour, will not inevitably possess a 'sex'.

Such a brief survey forbids the detailed mention of special cases, but it can be seen that the complications of heterothally fit into an ordered scheme when viewed as adaptations to the control of outbreeding. Basically, the function and genetical structure of heterothally are the same as those of systems found elsewhere. The superficial differences are imposed by peculiar circumstances arising from the existence of an independent haploid phase.

HALLEY'S WORK AS A GEOGRAPHER

THE remarkable progress made in geography in the seventeenth and early eighteenth centuries owed much to a distinguished band of scholars at Oxford. This progress was made in two branches of the subject. On one hand, there was a large output of cosmographical works in which the authors, who were also teachers at Oxford, tried to present the rapidly growing geographical knowledge of the world. On the other hand, mathematicians developed that side of geography which was closely related to navigation. It was one of the duties of the Savilian professor of astronomy to deal particularly with this aspect of the subject, although in practice his colleague, the Savilian professor of geometry, seems to have been equally interested and active. Halley held the chair of geometry, and the more important part of his contribution to geography is attractively dealt with by Prof. S. Chapman in his paper "Edmund Halley as Physical Geographer and the Story of his Charts" (*Occasional Notes, Roy. Astron. Soc.*, No. 9, June, 1941).

In addition to the work described by Prof. Chapman, Halley contributed some geographical papers to the Oxford Philosophical Society, made a survey of the tides of the English Channel, and undertook a journey to the Adriatic Sea. He is, however, best known for his charts, and with these Prof. Chapman deals fully, illustrating his paper by some excellent reproductions and by three isogonic charts of different periods. He also disposes of the claim that Halley explained correctly the physical causes of the trade winds.

At the end of his paper, Prof. Chapman refers to the geographical inaccuracies of Halley's charts. These, as he points out, were "due mainly to the necessity to estimate longitude". Soon after Halley's maps were published, the cartographical researches of G. Delisle led to great improvements, while before he died John Harrison had invented the chronometer and so had made possible the accurate determination of longitude. Prof. Chapman also refers to certain "geographical curiosities" on Halley's maps, including the courses of certain rivers in Asia and Africa. It should be recalled that when Halley wrote there had been very little exploration of Asia and practically none of Africa. Geographers, in the case of the latter continent, had to rely largely on classical tradition and the work of Leo Africanus. How great was the ignorance and the fascination of the Dark Continent can be read in Defoe's story of the adventures of Captain Singleton.

Prof. Chapman's paper is timely in appearance, for the two hundredth anniversary of Halley's death is being commemorated this year. Halley held his Savilian chair until his death and did much to promote the study of applied geography. It is too much to say, as does the "Dictionary of National Biography", that he laid the foundation of physical geography but, none the less, his work was substantial and of lasting value: to it Prof. Chapman does full justice.

J. N. L. BAKER.

NOMENCLATURE OF *Cl. welchii* 'TOXINS' TYPE *A*

THE investigation of the toxins produced by *Cl. welchii* type *A* (classic gas gangrene of man) has led to the recognition of the complex nature of the soluble substances recovered from filtrates of cultures of this organism. The attempt to analyse these substances into their component elements has led to certain unfortunate confusions in the nomenclature, as pointed out by Llewellyn-Smith[1].

In view of the difficulties presented to research workers by this state of affairs, an informal meeting convened by Dr. M. Stephenson was held, under the chairmanship of Prof. T. Dalling of the Institute of Animal Pathology, Cambridge, at the Biochemical Laboratory in Cambridge on April 5, 1941, at which workers actively engaged in research in this field and those responsible for the production of antisera were present by invitation.

After a full discussion it was decided to adopt the following nomenclature as the basis for future publication.

(1) Among the antigenic substances found in filtrates the main toxic element is characterized by the following biological properties:

(*a*) It is lethal for mice when administered by intravenous injection.

(*b*) It produces a characteristic necrotic reaction on intradermal injection into guinea-pigs.

(*c*) It is hæmolytic *in vitro* for sheep red cells, the hæmolysin being oxygen-stable and requiring the presence of calcium ions for the full development of its action[2].

(*d*) It reacts specifically with normal human serum[3] and with egg-yolk solution to give a characteristic turbidity[2].

This reaction also requires the presence of calcium ions and is probably due to the action of a lecithinase which splits phosphocholine from lecithin[4].

These various reactions appear to be due to the action of one substance designated as the *alpha toxin* and they can be neutralized by alpha antitoxin.

The *alpha* toxin has long been recognized as the main element in the pathogenic action of *Cl. welchii* type *A*[5].

(2) A second hæmolysin has been recognized in *Cl. welchii* filtrates which has properties distinct from those of the *alpha* toxin :

(*a*) It exhibits a slight but irregular action when administered intravenously to mice, owing to the presence of natural antitoxin in this and other experimental animals.

(*b*) It produces a hæmorrhagic reaction, but it is not necrotic in action on intradermal injection into guinea-pigs.

(*c*) It is hæmolytic for sheep red cells *in vitro* ; the hæmolysin is reversibly oxidizable, the hæmolytic activity declining with the ageing of filtrates ; the hæmolysis is independent of the action of calcium ions.

(*d*) It does not give a reaction with human serum or egg yolk solution.

(*e*) It resembles closely streptolysin O.

(*f*) The reactions produced by this second hæmolysin are neutralized by high titre antihæmolysin O as well as by the homologous antiserum.

It was agreed that this second hæmolysin should be designated as *theta hæmolysin*, and that it should be clearly recognized as being distinct from *alpha* toxin of *Cl. welchii.*

The first mention of this type of hæmolysis is made by Neill[6] but no special nomenclature was adopted. Prigge erroneously called this hæmolysin *alpha*[7] and this mistake was repeated in the League of Nations Bulletin of the Health Organisation (8, 797 ; 1939).

The letter theta was first used as a designation for this hæmolysin in the literature by Macfarlane, Oakley and Anderson[2], and its properties have been clearly defined by Todd[8].

The use of zeta[7] for what is obviously the alpha toxin is therefore discarded according to the ordinary usages of nomenclature.

No assumption is made that these two elements are the only 'toxins' present in filtrates from all strains of *Cl. welchii*, type *A*.

RECENT WORK ON THE GEPHYREA*

DR. A. C. STEPHEN has published two memoirs relating to this group. He had a difficult task before him, for it is well known that its members are extremely elusive owing to their habitat and that the few specimens usually available are frequently damaged—a fact borne out by a species sometimes only being represented by an isolated introvert or flattened skin. It is therefore specially to be appreciated that so many specimens were brought up whole and undamaged and that colour notes made at the time of capture are available. The Discovery species are mainly from southern waters but some of the Sipunculids were secured in the Atlantic on the outward and homeward runs. Only one species is recorded in both reports—*Pyscosoma nigrescens* Keferstein, a widely distributed form in tropical waters, now obtained for the first time from Ascension and Tristan da Cunha. There are two new species from deep water from the Gulf of Oman and off the Maldive Islands, and one from the Gulf of Aden ; also one new species of Thalassema from the Antarctic. The most interesting records, however, are those relating to bipolar species.

It has been known for some time that there is a close similarity, amounting in many cases to specific identity, between arctic and antarctic species belonging to the Echiuridæ, Sipunculidæ and Priapulidæ, and this is further exemplified in the Discovery collections. Of the twenty-three species known from the Antarctic and here listed (a few obviously warm-water forms being excluded from the list) half are either northern species or very closely related to them and ten of these are identical with, or regarded as varieties of, arctic species, and two are very closely related to arctic forms but are still regarded as specifically distinct. In this list species collected by the British, Australian and New Zealand Antarctic Research Expedition are included, the report of which by the same author is now in the press. Of the ten which are identical with, or regarded as varieties of, arctic species, four are included in the Discovery Collections.

The author directs attention to the fact, which stands out and may represent a real condition, that in the Antarctic most of the bipolar species seem to be confined to the South American quadrant.

The known range of distribution in several cases has been considerably extended, thanks to the wide area over which investigations were conducted by the Discovery ships. The Echiurids especially are interesting. Only three species of this group were known from the Antarctic. Now three species are added, two of which, *Hamingia arctica* and *Thalassema faex*, are well-known species which have not so far been found in other than Northern seas, and the third is a new species, *Thalassema arcticum.*

Both monographs are illustrated by good photographs.

Discovery Reports, Vol. 21, pp. 235–60, Plates VII, VIII. 1941. Issued by the Discovery Committee, Colonial Office, London, on behalf of the Government of the Dependencies of the Falkland Islands (Cambridge University Press). Sipunculids and Echiurids of the John Murray Expedition to the Red Sea and Indian Ocean, 1933–34, by A. C. Stephen, D.Sc., John Murray Expedition, 1933–34. Scientific Reports, Vol. 7, No. 4, 1941. (British Museum (Natural History), London.)

FORTHCOMING EVENTS

Saturday, January 10

British Institution of Radio Engineers (at the Federation of British Industries, 21 Tothill Street, London, S.W.1), at 3 p.m.—Dr. W. Wilson: "Recent Developments in the Design and Application of the Cathode Ray Oscillograph".

Monday, January 12

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 3 p.m.—Discussion on "Geographical Aspects of Regional Planning".

Wednesday, January 14

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. E. F. Armstrong, F.R.S.: "The Post-War Home—its Interior and Equipment". 3: "Materials, Old and New".

Friday, January 16

Royal Society of Arts (India and Burma Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Sir Bryce Burt: "Agricultural Progress in India during the Decade 1929–39".

Saturday, January 10—Sunday, January 11

Association of Scientific Workers (at Caxton Hall, Westminster, London, S.W.1). Conference on "Science and the War Effort".

Saturday

10 a.m.—Opening Address by Sir A. Daniel Hall, K.C.B., F.R.S.

10.30 a.m.—"University Training of Scientists". Dr. W. A. Wooster (Chairman), Prof. J. A. Carroll, Dr. V. E. Cosslett, Mr. R. R. Siday, Mr. D. G. Arnott.

10.30 a.m.—"Building, Housing and A.R.P." Mr. Ove N. Arup (Chairman), Dr. R. Fitzmaurice, Miss J. M. Blanco White.

2 p.m.—"Training of Technical Personnel". Mr. E. G. Savage (Chairman), Mr. J. A. Lauwerys, Dr. E. A. Rudge, Mr. D. A. Bell, Dr. B. E. Gilbey.

2 p.m.—"Food and Agriculture" (1st Session). Sir John Russell, F.R.S. (Chairman), Sir John Orr, F.R.S., Sir A. Daniel Hall, K.C.B., F.R.S., Dr. H. M. Sinclair, Prof. H. D. Kay, Prof. F. G. Gregory, Dr. A. Walton.

4.30 p.m.—"Food and Agriculture" (2nd Session). Discussion.

Sunday

10 a.m.—"Utilisation of Scientific Personnel". Prof. S. Chapman, F.R.S. (Chairman), Prof. W. Wardlaw, Mr. E. D. Swann, Prof. H. Levy, F.R.S., Mr. D. P. Riley, Mr. F. M. H. Markham.

2 p.m.—"Application of Scientific Knowledge to Production and Services Problems". Prof. J. D. Bernal, F.R.S. (Chairman), Mr. T. Halse, Dr. P. Garland, Dr. K. Mendelssohn, Mr. J. W. Myers, Dr. J. Kuczynski, Mr. J. L. Pinder.

4.30 p.m.—Final Discussion. Mr. J. A. Henley, Prof. J. D. Bernal, F.R.S.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Dietitian in charge of the Dietetic Department—The House Governor and Secretary, General Infirmary, Leeds (January 20).

Lecturer in Mechanical Engineering—The Principal, South-West Essex Technical College, Forest Road, Walthamstow, London, E.17.

Executive Engineers by the Nigerian Government Public Works Department—The Central Register (E.364), Ministry of Labour and National Service, Queen Anne's Chambers, Tothill Street, London, S.W.1.

Assistant Engineer by the Sierra Leone Government Railway—The Central Register (E.365), Ministry of Labour and National Service, Queen Anne's Chambers, Tothill Street, London, S.W.1.

Engineer by the Sierra Leone Government Public Works Department—The Central Register (E.372), Ministry of Labour and National Service, Queen Anne's Chambers, Tothill Street, London, S.W.1.

Psychologist (man) at the Sutton L.C.C. Hospital, Sutton—The Medical Officer of Health (B), Mental Health Services, West Park Hospital, Epsom, Surrey.

Professor of Physiology—The Secretary, University College, Cork.

THE UNIVERSITY OF ORISSA

DURING the first decade of this century, mainly as the result of the recommendations of the Curzon Commission culminating in the Universities Act of 1904, the older Indian universities, Madras, Bombay, Calcutta and the Punjab, modified their examination requirements and effected fundamental alterations in the teaching in their affiliated colleges. Unfortunately, the university examinations in their various grades from the matriculation upwards continued to be recognized as qualifications for admission to the various Civil Services, since only for a few appointments, such as those in the Finance Department, was there a special Civil Service examination. The linking of the Civil Services with the universities has had the unfortunate result of overcrowding the colleges with students, in many cases of mediocre ability, and has so to some extent nullified the beneficial effect of the improved courses of study. Two other factors have also contributed to still further overcrowding : first, the continued though welcome spread of primary and secondary education, and secondly, the increasing desire for a training in the methods of science.

This increasing demand for higher education has resulted in the opening of a large number of new institutions of university rank throughout the Indian Empire. Unlike the older federal universities, the majority of these new universities have been of the unitary teaching type, as exemplified in the University of Lucknow. At the same time, the older universities have in all cases made themselves directly responsible for much of the post-graduate teaching.

In 1938 the Government of Orissa recognized the necessity of reorganizing the higher education in the Province, and it appointed a representative committee under the chairmanship of Pandit Nilkantha Das to examine the question of establishing a university in the Province. This committee presented its report* last June, and it unanimously recommends that a university of a modified affiliating type should be established. It is suggested that the university should in the first instance be purely affiliating, but that it should later be responsible for the post-graduate teaching. The administrative structure recommended for the new university is very similar to that of the University of Madras.

While many may regard it as somewhat retrograde to establish a new university of the affiliating type, it must be borne in mind that Orissa is a small and not too well-endowed province. The principal college of university standing is the Ravenshaw College at Cuttack, and this will be the nucleus of the teaching university. It would, however, scarcely be economic if the teaching centres at Parlakimedi and Berhampur were to be closed down. From the figures given in the Committee's report, it is clearly not anticipated that the number of university students will be large, the estimated size of the intermediate classes in arts and science combined being about 400 students, and although there is to be a Faculty of Law, there is no provision for the teaching of medicine. It is refreshing to note that the Committee recognizes that teaching is not the sole function of a university, but that facilities should also be available for original work both in arts and science. It is not unnatural that the Committee should recommend that the post-graduate teaching in Oriya history, language and literature should receive special consideration. We trust that the new university will soon be opened and be making its own contribution to learning.

---

* Supplement to the *Orissa Gazette*, July 4, 1941.

ORIGIN OF LANDSCAPE FEATURES

Landscape

As Developed by the Processes of Normal Erosion. By Prof. C. A. Cotton. Pp. xviii + 302 + 45 plates. (Cambridge: At the University Press, 1941.) 21*s*. net.

WITHIN the last two decades there has been in Britain a marked revival of interest in the study of landscape features. The subject of geomorphology, even in its more limited scope as applied to the understanding of the surface features of the earth, has attracted new workers both from the fields of geology and geography, and fresh methods of investigation have been devised. The study of erosional geomorphology represents perhaps the most important common ground between geology and geography. In the past geologists have varied in the emphasis which they have laid on the study of 'physical geography', but until recently they have treated it mainly as part of an introductory course; lately there has been a greater tendency to regard it as representing a more important branch of that subject, and to recognize that future progress in the investigation of landscape must depend on workers whose geological training has brought them some acquaintance with the methods of investigation needed for these fields of inquiry.

Prof. Cotton, who has written this latest volume on landscape features and their origin, is in no doubt as to the place of this study. "Notwithstanding the close relation of the study and description of the natural landscape to geography", he trusts that geologists will accept this account "of the elementary principles of geomorphology as a contribution to the literature of their science". For he stresses the fact that the development of land forms has followed as a corollary of earlier geological events, while an understanding of geomorphic processes is essential for the interpretation of geological history. It may perhaps also be added that a real appreciation of the geological time-scale is necessary if landscape features are to be understood and correctly related to one another.

In this volume Prof. Cotton has not attempted to cover the whole field of land forms: he has limited himself to those features developed by the processes of "normal erosion". This he takes to include the results of atmospheric weathering (predominantly chemical) combined with downhill transportation of rock debris, mainly by rain and running water. These processes develop 'normal' landscapes. He regards as special agencies those which depend on climate, whether arid or glacial, and on marine erosion, the effects of which are confined to the land margins. While this limitation enables the author to deal more adequately with the processes which have modified the earth's surface over the widest areas, it has some disadvantages, for since the development of the present land surfaces began there have been great changes in the distribution of climatic regions, and it would be impossible to describe the landscape features of many regions, especially in the northern hemisphere, in terms of normal erosion. This is, of course, fully recognized by the author, and he has found himself compelled to refer to some of the features due to more special agencies.

Geomorphologists owe a great deal to three American pioneers, Gilbert, Powell and W. M. Davis; Prof. Cotton acknowledges this indebtedness not merely by the dedication of his book to their memory, but also by many references to their work and opinions. This must not be taken to imply that the book is formal, or lacks up-to-date references: it presents an original and comprehensive account of the results of normal erosion, differing in outlook and emphasis from other books of similar scope, and dealing with the landscape of regions in all parts of the world.

Probably this wide choice of less familiar examples will be one of the most fruitful features of this volume, particularly since the illustrations lend such a distinction to the writing. For Prof. Cotton has supplied more than two hundred text-figures; most of them are new and many are beyond praise. His 'block-diagrams' are particularly successful, and convey the relation between structure and surface features in a way that will stimulate the geological student and will make the book doubly useful to those untrained in structural work. But these admirable figures do not exhaust the illustrations provided, for there are also forty-five plates, most of them with two photographs, showing a wide range of features; these are chosen from all parts of the world, and their value is increased by the inclusion of many original views of New Zealand.

The sequence of chapters is somewhat unusual: after an early chapter on mass movement of waste there is a study of rivers, their deposits and related phenomena, which occupies fourteen chapters. Then comes a chapter on peneplains and one on resurrected fossil land surfaces. Two chapters on the effects of uplift and warping and the movement of base-level are followed by three very interesting chapters on fault features, block-faulted landscapes, and fault scarps, the book concluding with a short account of limestone landscapes.

In view of recent discussions, British geomorphologists will turn with particular interest to the chapter on peneplains, where the old-age stage of the cycle of erosion is discussed and illustrated. A somewhat fuller treatment of the peneplain problem would have been acceptable. If, as is generally agreed, many areas present us with a stage in the dissection of an uplifted erosion surface, it may be suggested that the study of such surfaces and their relics is of fundamental importance. It is interesting, however, to read of W. M. Davis' explanation of the limiting steepness of the slopes on a peneplain, given a quarter of a century ago: the slopes were such that one might lay out a straight road on the peneplain in any direction, "and trot on it". In these days, comments Prof. Cotton, this would be a 'high-gear' road. He gives British workers some notion of perspective, perhaps, by limiting his reference to British peneplains to some five lines and three footnotes: since so many problems are presented by the erosion surfaces of this small region, notwithstanding the many investigators, it may be felt that some caution is advisable in interpreting some larger and less accessible peneplains.

The production of such an elegant volume, attractively illustrated and on admirable paper, at this time, with the author resident in New Zealand, calls for the warmest congratulations both to him and to the Cambridge University Press. The publication is the more noteworthy since the volume deals with matters of which most must long remain within the province of 'pure' science. The book may be strongly recommended for reading by students of geology and geography, and it should find a place in the libraries of universities and schools.

A. E. TRUEMAN.

TEACHING OF PHYSIOLOGY

Starling's Principles of Human Physiology

Eighth edition, edited and revised by Prof. C. Lovatt Evans; the chapters on the Special Senses revised by Prof. H. Hartridge. Pp. x + 1247. (London: J. and A. Churchill, Ltd., 1941.) 32*s*.

Physiology for Pharmaceutical Students

By Dr. Harold Hayden Barber. Second edition. Pp. x + 526. (London: Baillière, Tindall and Cox, 1941.) 15*s*.

STARLING'S "Principles" first appeared a generation ago, and throughout the intervening years it has been the main vehicle for the diffusion of trustworthy and co-ordinated physiological knowledge throughout the English-reading world. Since Prof. Lovatt Evans has been in charge of the work, it has retained the full treatment of the chemical and physical basis of physiology for which the earlier editions were noteworthy; he has dealt more fully with problems of integration and has kept well abreast of contemporary developments, which are presented in a lucid and balanced manner and with adequate, but not superfluous, documentation.

In the current eighth edition, the physiology of the central nervous system has been completely rewritten to incorporate recent advances such as those dealing with the intricacies of nervous transmission in the spinal cord, and to convey generally the current attitude; newer work in such active fields as the endocrines, vitamins, urinary secretion and metabolism is fully considered. The sections on reproduction and on the special senses (the latter written by Prof. H. Hartridge) are especially noteworthy.

The book, however, is still growing in size, and Prof. Evans will soon have to face the problem which many American writers feel they can safely ignore, whether there is not an optimum size which should not be exceeded for a standard text-book. Most books are written to serve an audience, and texts on human physiology are mainly read by students and practitioners of medicine who want a survey of the subject which can be studied and mastered in the limited time at their disposal. Physiology and the related sciences are expanding at a great rate; before the War, some ten thousand papers appeared annually, which contained new contributions great or small. The author of the standard text-book has the arduous responsibility of sifting this work, of incorporating the outstanding advances, of conveying the changing outlook of his subject, and of directing attention to the chief growing points and to the guiding generalizations which are emerging.

But this does not exhaust the list of the text-book writer's responsibilities; it is still a matter for dispute whether medicine is a science or an art, but undoubtedly the practitioner of medicine must be a man of science as well as an artist. It is essential therefore that at some stage in his education he should be given a sound grounding in the methods and outlook of science. The physiologist may be forgiven for saying that no other subject in the medical curriculum is better adapted than his own for such a high purpose. Enough time is available in the course to deal with some aspects of the subject in sufficient detail to show their historical development. Rigid experimental and observational proofs can be described and carried out in the laboratory of the main theses of the subject. The student may be shown how experiments are planned and carried out and how conclusions are drawn. It may be stated without offence that a good physiological course will make a medical man passably immune to the pitfalls of loose thinking and to the acceptance of inadequately confirmed claims. In addition, however, physiology is one of the principal limbs of the tripod on which clinical medicine rests. Much of the evidence on which human physiology draws is derived from observations and experiments on patients, and to that extent physiology is none other than medicine.

If the text-book is to be kept within manageable limits, the author will not attempt to summarize, ever more briefly, unintelligibly and uninterestingly, the ever-growing mass of material with which he is confronted. He will select his material with the aim of giving the basis of the scientific training, of presenting adequately the fundamental facts and principles of his subject, and he will enlarge especially on aspects of vocational value to the medical practitioner. Observations on man which are scientifically satisfactory must replace increasingly observations made on the lower animals. When human material is inadequate, stress will be laid on observations made on the higher animals. One can see these tendencies now in the treatment of such problems as control of respiration, erythropoiesis, muscular exercise, functions of the higher levels of the brain, secretion of urine, nutrition, and metabolism, to select but a few examples at random. As Prof. A. V. Hill has remarked, teaching is an experimental science, and the abilities of authors will be taxed to the full in the future if their writings are to prove of maximum advantage to the reader.

Dr. Barber's book is obviously meeting a need, as a second edition has been called for in four years. It resembles closely in content and treatment the smaller physiological manuals intended for medical students, except that the nervous system is dealt with very briefly, the special senses are omitted, diet and metabolism are touched on lightly, though a relatively detailed account is given of the vitamins and endocrines. There is also a short section on the elementary pharmacology of some special substances.

Physiology forms part of the course of instruction and of the examination for the elementary qualification for chemists and druggists and for the higher qualification of pharmaceutical chemist. One and two years respectively are allotted for the study of pharmaceutical chemistry, pharmacognosy, pharmaceutics, forensic pharmacy and physiology. As the time available for physiology even in the longer course is very limited, one supposes that physiology has been introduced into the curriculum (especially in the shorter course) mainly for cultural reasons. It is proper that a man who will deal with the preparation and marketing of remedies for human ills should have some general idea of the working of the human body. The physiological training is not vocational because the pharmacist should have few if any opportunities of making practical use of his physiological knowledge, unless he allocates to himself the function of an immature healer and adviser on minor maladies.

Though Dr. Barber's book is so full of facts and figures, chemical reactions and experiments, it does not seem to give the elementary student who is pressed for time a co-ordinated simple account of the workings of the human body. Inadequate attention is devoted to explaining fully and carefully the fundamental principles of the subject. These failings are probably the result in large measure of the existence of a rigid examination syllabus for this group of students, which if it were followed conscientiously by teachers in planning their lectures would make their course no better than a caricature. Thus the 1927 syllabus for the elementary qualification of chemist and druggist refers specifically to "properties of cardiac, striated and unstriated muscle, the mechanism of the heart valves, the coronary circulation, the effect of inflow and rate on the output of the heart, the importance of the maintenance of the blood pressure". There are references to blood, glands of internal secretion, the alimentary tract and food, but so far as this syllabus is concerned the body would appear to possess, among others, no respiratory system, no nervous system, no sense organs, no kidney and no urine. By 1941 the syllabus had gained references to the principles underlying biological assay, but in the meantime the body had specifically lost the anterior pituitary, parathyroids and the organs of reproduction.

It is difficult to say what useful purpose a syllabus of this singularly unbalanced character can serve. In the universities it will no doubt be ignored and a general elementary course based on cultural consideration will be given. In the many less experienced centres that train students of pharmacy, attempts may be made to use the examination syllabus as a basis of teaching, with the result that the course in physiology will be of negligible value. The student reading for the qualification of pharmaceutical chemist needs no special manual, and could safely be entrusted with the shorter works intended for medical students. The more elementary student needs a really straightforward and fully explanatory work which will enable him to see the workings of the body in outline and as a co-ordinated whole. If the present syllabus in physiology for elementary students of pharmacy were completely jettisoned, a considerable advance would be made in the proper training of such students.

SAMSON WRIGHT.

IMPACT OF INVENTIONS ON PEOPLE

Technology and Society

The Influence of Machines in the United States. By S. McKee Rosen and Laura Rosen. Pp. xiv + 474. (New York: The Macmillan Company, 1941.) 12*s.* 6*d.* net.

WE are repeatedly told by those who look beyond the passing events chronicled from day to day that the structure of human society is changing with a rapidity hitherto unimagined, that the world after the War will be a completely different world from that which we knew before. In this there is probably a large measure of truth, but though the War has undoubtedly speeded up the rate of change, the change was inevitable for other reasons. It is explained by the march of technological invention. 'March' seems an inadequate word to describe what has taken place during the brief lifetime of the present older generation—it is rather a flight which leaves one breathless. There is no more ruthless, but—if wisely directed—ultimately beneficent iconoclast than invention, no more powerful lever for moving nations out of the deep ruts of habit and convention into which, if left lethargic, they tend to sink. We are being so lifted and shaken now, and it is as well to realize what is happening if we are to profit by the experience.

In spite of its somewhat deterrent title to those who are not mechanically minded, anyone unfamiliar with the less common inventions of recent times will gain much useful information by studying this book: it is both readable and stimulating. In an introductory chapter Prof. W. F. Ogburn gives an admirable summary of modern discoveries, stressing the imperative need for a national policy wisely shaped in the light of their probable future trends. Naturally he has the United States in mind, but the lesson is one we also might well learn. Attention is directed to the amazing advance of science since the beginning of the century as illustrated by six industries in which development has been great, based upon the invention of the telephone, motor-car, aeroplane, motion picture, rayon and radio. He recalls that round about 1900 Theodore Roosevelt was commended for "his characteristic courage" upon riding in an automobile; forty years later there is one car to every five persons in the States. In 1903 a distinguished American man of science went so far as to surmise that mechanicians would be "ultimately forced to admit that aerial flight is one of that great class of problems with which men can never hope to cope". One particular group of comparatively modern inventions deserves note, although it has been regarded by the authors, no doubt justifiably, as outside their domain: it only receives passing mention. Devices for controlling conception are gradually being perfected. The conspicuous effect of these discoveries, for better or worse, on the trend of world population is now generally recognized, and they are perhaps destined radically to influence family life, the very texture of civilized society.

A major achievement of modern technology is the possibility of continuous production, but such continuity is profitless if there is no effective demand which can be equated to the supply of goods produced. For demand to be effective wages and prices must be suitably related, and here the Government, by its ultimate control over the creation of credit and the conditions of labour, has a responsible part to play. This aspect of the problem is not discussed by the authors. They do, however, point out that machine production, though it involves an initial displacement of labour, should eventually make possible a big increase in sales by reduction in price, and so result in a net gain in employment. Electric light and power, the manufacture of cars, and newspaper publishing are cited as industries where this has actually happened. But everybody does not benefit. Figures are quoted showing that, while annual production per man rose by 39 per cent in the United States between 1920 and 1935, the index of employment fell by 18 per cent. This dilemma could be partly met by continued education, earlier retirement for the elderly, and increased leisure for all, in preference to enforced total idleness for so many. Because such a solution has not yet been adopted, the progress of invention is frequently regarded by the workers with dread. Instead of raising their standard of living, as it should do, it condemns a considerable number to a bare maintenance on charity or the dole. Nor is it only the wage-earner who stands to suffer. We read of company managers who, fearing the adoption of new machines by their trade rivals, do their best to block the marketing of improved models. Commercial competition is not always in the public interest, as is revealed also by the story of national broadcasting in the United States.

But here again there are signs of improvement. Among thinking people there is a steadily growing realization of the essential interdependence of all sectional interests, both within the State and in the wider world. Selfish individualism must give way to "the idea of the general welfare as the basis of public policy." To put this principle into practice demands a sensitive handling of groups, which unfortunately is comparatively rare. In this connexion the description given of the development of the Tennessee Valley Authority is instructive. Created by Congress in 1933 as a public corporation, it possessed at the same time the flexibility and initiative of a private enterprise. Its function was to plan and develop the Tennessee Valley, and its express policy was to use existing agencies wherever possible. The resulting growth of "inter-governmental co-operation attuned to regional needs" is said to have been most impressive. It is clear that success in this case was largely due to appreciation of the importance of the right psychological approach to the various bodies concerned. If we go to work along similar lines, in Great Britain as in the United States, there should be good hope for the future.

D. Caradog Jones.

NEUROLOGY FOR STUDENTS AND PRACTITIONERS

Diseases of the Nervous System

Described for Practitioners and Students. By Dr. F. M. R. Walshe. Second edition. Pp. xvi + 325. (Edinburgh: E. and S. Livingstone, 1941.) 12*s*. 6*d*. net.

THE first edition of this book appeared in September 1940, and the fact that a second edition has been needed within a year (this edition was published in August) speaks for itself. Dr. Walshe planned this book for the use of practitioners and medical students; and there can be no doubt that he has been entirely successful in his object. The need of just such a book as this has been long felt by those engaged in teaching students the fundamental elements of neurology, and those of us who are familiar with Dr. Walshe's powers of lucid exposition and his critical faculty will not be surprised by his success.

Though some important additions have been made in the present edition, the book has retained its original character and purpose. The additions consist of some thirty or so pages and a number of excellent photographs and diagrams which have added materially to the usefulness of the book.

The book is planned in two parts, the first dealing with the fundamental groundwork involved in the correlation of observed physical signs and symptoms, with their physiological and anatomical counterparts, the second being devoted to a descriptive account of the more common diseases of the nervous system. The additions to the first part consist of a brief statement of the tissue reactions occurring in nervous diseases, and some amplification of the section dealing with the organization and symptomatology of sensory, visual and speech functions.

In Part 2 the chapter on intracranial tumours has been partly recast, and additions have been made to the chapters on acute infections, injuries to the head and spine, and lesions of the spinal nerves.

In the preface to the first edition, Dr. Walshe emphasizes the fact that he has written a book which shall deal only with what is possible in general practice, and so warns the reader that he will find little about such things as ventriculograms or of the electro-encephalogram—as the general practitioner will not be required to make or interpret either. That is no doubt true at the present time, but I think that in a future edition for which, if I am not mistaken, there will be a demand before very long, a short chapter on the possible usefulness particularly of the electro-encephalogram might be added with advantage. Mention, too, might be made of the dramatic success which sometimes follows the use of deep X-ray therapy in some cases of post-herpetic neuralgia, not only of spinal type also in some cases where the Gasserian ganglion has been involved. Rather fuller description might with advantage be added to the clinical picture of severe head injuries and to their treatment, for this is a subject of common occurrence and the cause of much anxiety to practitioners and friends alike.

Dr. Walshe has included in his book a chapter on the psychoneuroses, dealing mainly with their diagnosis. In the preface to the first edition he has commented on this in phraseology so apt that I feel I must quote him here: "It may appear unduly sanguine to hope to give within the compass of a single chapter a useful account of this very important aspect of medicine when we recall what a vast literature has grown up around it in the present century. However, much of this is concerned with hypothesis, and the essential task of diagnosis, the clinician's first task, has usually been a Cinderella at this carnival of literary expansiveness." In this chapter is contained a note on so-called 'traumatic' neurosis, a subject on which, as the author says, a candid statement is long overdue. I do not remember seeing in any other text-book of neurology any emphasis laid on the fact that trauma *per se* does *not* cause neurosis. Judging from a considerable experience in courts of law, it would seem that judges, lawyers and medical men giving evidence think that 'traumatic' neurasthenia is as much an entity as measles. It is high time that they became better instructed.

Useful chapters are included in the book on bromide intoxication (a condition which is so often unrecognized) and some general observations upon the treatment of nervous disorders in which what can and what cannot be hoped for are candidly set out. The book ends with an excellent and simple scheme for the examination of the nervous system.

I can recommend the book to the student and practitioner alike in the sure confidence that they will both profit from a study of it and also obtain considerable pleasure in the process.

C. M. HINDS HOWELL.

THE STUDY OF LYMPH

Lymphatics, Lymph and Lymphoid Tissue

Their Physiological and Clinical Significance. By Prof. Cecil Kent Drinker and Dr. Joseph Mendel Yoffey. (Harvard University Monographs in Medicine and Public Health, No. 2.) Pp. x+406. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1941.) 4 dollars.

THIS book is good reading since it shakes convictions and stifles beliefs; and, exposing our ignorance, it will stimulate research. The first chapter is coldly anatomical, but warm argument soon begins. In the second chapter, the authors have to consider the permeability of capillaries in order to account for the composition of tissue fluids and lymph. Here there is difficulty with the albumins and globulins often present in lymph: it is agreed that they are derived from the plasma of the blood, but how do they leak out of the capillaries? The stand is taken that they pass through the endothelial cells under a pressure of a few centimetres of water: but can molecules having molecular weights of many thousands enter, pass through, and emerge from the cytoplasm of endothelial cells where equally large molecules are abundant? If this be the way, there ought to be differential filtration, the smaller albumin molecule passing in greater abundance than the globulin, and yet, as the authors show, the ratio is approximately the same in lymph and plasma. The other way is between the endothelial cells, where there is discontinuity in structure between cytoplasm and intercellular matrix, surely a likely place for leakage. When we come to the passage of these proteins into the lymphatics from the tissue spaces a further difficulty arises: here there is no positive pressure to help the passage, and so some easier way than through the cytoplasm of the endothelial cell of the lymphatic vessel seems especially to be required.

Such interesting questions as these are excellently dealt with in the first 150 pages of the volume.

The rest of the volume deals with the function of lymphoid tissue and of lymphocytes. Lymphoid tissue composes about one per cent of the human body: it is a tissue especially well developed in mammals, and yet we do not know its function. The situation is unique: here is the physiologists' Cinderella.

It is a pleasure to record that this mystery remains the subject of hot debate and a playground for the investigator.

The fate of lymphocytes which enter the blood stream from the lymphatics is of interest. In the case of a dog of 10 kgm. about five thousand million enter the blood stream, via the thoracic duct, per day, sufficient to replace the circulating lymphocytes twice. Where do they go? Many possibilities are considered, but one, I think, has been somewhat overlooked. Not only do lymph glands produce lymphocytes, they also destroy them in large numbers by phagocytosis by macrophages. Perhaps production does no more than equal destruction; if so, the fate of great numbers would be accounted for, as well as a means of maintaining constancy in numbers.

In dealing with the effect of X-rays, the authors have missed an important finding. If a rat be given a very small dose of X-rays the lymphocytes fall to about 50 per cent: if then a second small dose be given no further fall occurs: if one waits until numbers have returned to normal, then a second dose produces again a 50 per cent reduction. There are therefore two kinds of lymphocytes in the rat: measurement of size shows that it is the small lymphocytes which are susceptible and the large resistant to X-rays. It seems possible that results might be more easily interpreted if we separated the large from the small, instead of considering them together. Advance has often been kept back by improper classification.

The final section of the book is entitled "Practical Considerations", and will be of special interest to pathologists and clinicians. Here such subjects as œdema, hypertension, shock, lymphatic obstructions and anæsthetics are discussed from the points of view of the lymphatic system.

J. C. MOTTRAM.

CHROMOSOME CHEMISTRY AND GENE ACTION

By DR. C. D. DARLINGTON, F.R.S.

John Innes Horticultural Institution, Merton, London

THROUGHOUT plants and animals the cell nucleus has a uniformity of structure corresponding to the uniformity of its work. This structure has to reconcile the mechanical requirements of cell division and reproduction with the physiological requirements of heredity and development. Its primary importance has led to its study by a great variety of physical and chemical techniques ; indeed, a greater variety than has been brought to bear on any other type of structure. Differential staining, X-ray diffraction and X-ray destruction, double refraction, micro-dissection, micro-incineration, ultra-violet spectroscopy and differential digestion as well as bulk analysis and the vast magnifications of genetic experiment have been used. They have all played their different parts in the solution of the problem.

The important agents are few and well defined. The nucleus consists of chromosomes which are enormously extensible protein fibres shown by digestion[1] to resemble the protamines and histones making up the bulk of sperm heads[2]. To these fibres, or rather to specific points on them, the chromomeres, are attached desoxyribose-, or thymo-, nucleic acid which is responsible for the specific aldehyde reaction given by the chromosomes in Feulgen's test[3]. Underlying the cycle of mitosis and cell-division is a cycle of attachment and detachment of this nucleic acid to and from the chromosomes. This goes with the cycle of coiling and uncoiling of their protein framework. The maximum attachment corresponds with the maximum spiralization of the chromosomes at metaphase of mitosis. At the other extreme, within the resting nucleus, they are uncoiled and relatively free from nucleic acid[4].

At the end of every mitosis the chromosomes give up their nucleic acid charge and at the same time secrete *nucleoli* which dissolve at the beginning of the next mitosis when the chromosomes are taking up nucleic acid again. These nucleoli contain no thymo-nucleic acid, but instead the ribose form which is characteristic of cytoplasm and of viruses.

The two nucleic acids differ only in the central sugar radical of the nucleotide. The desoxyribose radical apparently, however, gives its nucleotides a flatness to which they owe their capacity for polymerization. They form columns of plates which, as shown by polarized light, lie crosswise to the protein thread[5]. These plates agree in spacing at 3·34 A. with the extended polypeptide chain of the chromosome. It is this capacity which seems to make thymonucleic acid indispensable in the reproduction of the chromosome. For reproduction takes place by division of each fibre into two at the end of the resting stage, when the attachment of the nucleic acid charge is beginning[6].

The chromomeres, photographed by ultra-violet light, have been shown in a simple case to correspond with the units of X-ray breakage, which provide the physical definition of a gene[7]. Among chromomeres three special kinds of structure and function are found (Fig. 1). First there is the *centromere*, the movements of which control the movements of the chromosome on the spindle. The centromeres reproduce, or at least divide, not within the nucleus, but on the mitotic spindle. This delay in their reproductive cycle goes with a deficiency of nucleic acid at all stages of mitosis. If undivided lengthwise they will split crosswise on the spindle. They are, therefore, compound genes[8]. They may be regarded as spindle organizers playing a similar part to the centrosomes although living within the nucleus instead of outside it.

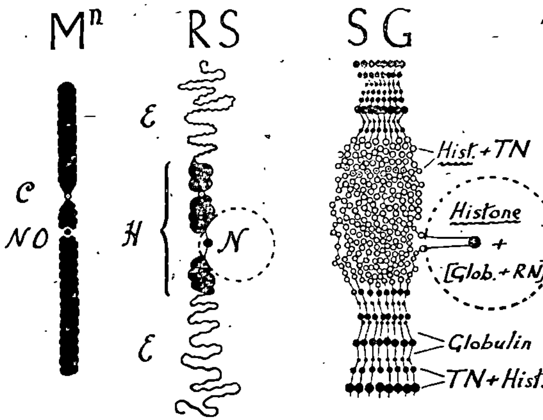

Fig. 1.

DIAGRAM OF A CHROMOSOME OF DROSOPHILA AT METAPHASE, NORMAL TEMPERATURE (*Mn*), RESTING STAGE (RS) AND AS A 'POLYTENE' STRUCTURE IN THE SALIVARY GLAND (SG), SHOWING THE DIFFERENT ORGANS REFERRED TO IN THE TEXT AND THEIR CHEMICAL CONTENT AS DETERMINED BY CASPERSSON. C, CENTROMERE; N O, NUCLEOLAR ORGANIZER; H, HETEROCHROMATIN; E, EUCHROMATIN.

Secondly, there is *heterochromatin*. Parts of certain chromosomes have long been known to show an abnormal retention or even extra charge of nucleic acid between metaphases. This property was first recognized in the sex chromosomes of animals, where it often goes with a modified timing of the reproductive cycle. Genetic evidence likewise reveals a differentiation. Certain parts of chromosomes, such as the *Y* in Drosophila, have long been held to be inert. They made little or no observable difference whether present in excess or absent altogether, and as might be expected, underwent no observable mutations. Recently it has been shown in plants and animals that the two properties of inertness and abnormality of nucleic acid cycle are combined in the same genes or chromomeres, whether making whole chromosomes or parts of them. These are then said to be heterochromatic as opposed to the active or euchromatic genes[9].

Thirdly, the nucleoli usually arise next to one or more particular chromomeres, the nucleolar organizers, which are again compound genes breakable by X-rays, and may be either at the ends or in the middle, either in a heterochromatic or a euchromatic part of the chromosome[10, 11] (Figs. 1 and 2).

All these different elements of nuclear structure, except the centromeres, are clearly visible in the giant nuclei of the salivary glands of Drosophila, and to these ultra-violet spectroscopy has been applied by Caspersson in combination with other methods. By these means he can distinguish quantitatively and qualitatively between the two nucleic acids or their nucleotides on one hand, with a very high maximum absorption at 2600 A., and the proteins with a vastly lower absorption and a maximum at 2750–2900 A. Of these he is able to distinguish between two types which he labels provisionally a histone type with a maximum above 2800 A. and a globulin type with a maximum which changes with the *p*H of the medium but is below 2800 A. in acid medium[4, 12].

The use of this technique has confirmed the picture so far outlined. But it has also gone much further. It has shown that the heterochromatin and nucleolus agree in having a high histone content. On the other hand, in the euchromatin the regions between the chromomeres contain globulin-type proteins. These higher proteins are lost in metaphase chromosomes or ripe sperm, in which only histones and thymonucleotides are recognizable. This leads Caspersson to argue that the active chromomeres or genes in the resting or gland nucleus are producing large globulin molecules while the inactive ones are producing small molecules of histone type which, although still individual, will be less specific in their interactions. The difference between activity and inertness would then be the difference between specificity and non-specificity; or better, perhaps we might say, between high specificity and low specificity. Further, Caspersson considers that the similarity of content between heterochromatin and nucleolus means that one secretes the material of the other, or we might suppose some precursor of it.

This view is confirmed by experiment. The addition of extra heterochromatin to the nucleus increases the size of the nucleolus in the pollen grain of Solanum[13]. A similar addition, in the shape of a *Y*-chromosome, to a Drosophila egg increases the concentration of ribose-nucleotides, or other pyrimidine-containing molecules, in the cytoplasm and likewise in the nucleolus[14].

Another connexion is revealed by the fact that the nucleoli are proportionately largest in cells which (with the exception of nerve-cells) are concerned with the most rapid protein production, for example, animal egg cells, meristematic and tumour cells. They are smallest in cells where no protein is being made, for example, in young animal embryos and in leucocytes. It is therefore significant that ribose nucleotide concentration increases as cells turn to protein formation. This is especially clear in yeast: nucleotides appear as soon as a source of nitrogen is added, having been entirely lacking even in the most actively fermenting yeast in the absence of such a source. Furthermore, the increase of ribose-nucleotides and of proteins goes with a specially high concentration of them next to the nuclear membrane where the proteins are shown by polarized light to be laid down in lamellar formation. They must be constructed on the very surface where nucleus and cytoplasm meet[15].

This is the argument. And Caspersson concludes that the nucleus is, as we should expect on even more general grounds, the centre of protein synthesis in the cell, that the nucleic acids are the essential agents of this synthesis, whether as polymerized thymo-nucleotides attached to the genes or unpolymerized ribose nucleic acid elsewhere. Further, Caspersson looks upon the changes in nucleic acid cycle of the heterochromatic genes as depending on differences in rate of protein production of the nucleus in different tissues, the genes being discharged of nucleic acid, their spiral threads uncoiled and their chromomeres separated in so far as the products of their own activities accumulate around them[4].

This account represents the first attempt to describe chromosome structure and activity in relation to cell processes as a whole. It is concerned with the types of molecules whose interactions govern these processes, but it does not tell us the sequence of their interactions. In order to discover this sequence, different methods are needed. Two kinds of experiment have so far proved successful. The first depends on the control of the general metabolism of the cell, or of the organism, by its inert chromosomes. The second depends on the control of the nucleic acid attachment of the inert chromosomes themselves by conditions which are developmental and genotypic as well as external.

The activity of the inert chromosomes or genes might plausibly be deduced from their widespread occurrence. But the precise study of their life-cycle in the individual organism and their distribution in the species makes it certain. Inert chromosomes frequently happen to have a defect of the centromere, which leads to their loss at mitosis. Even when this is not so, their irregular pairing leads to their loss at meiosis. Nevertheless, in species as remote as *Cimex lectularius*, the bed bug, and *Zea Mays*, indian corn, there seems to be a stable equilibrium of inert chromosomes in races or populations. The same is true of wild millet and cultivated rye (Sorghum and Secale). Such inert chromosomes must be preserved by positive selection. In some way they must be useful to the cells and the organisms containing them.

The case of Sorghum bridges the gap between plants and animals in another way. The inert chromosomes having weak centromeres are lost sooner or later in the development of all somatic cells. They are retained in the germ track. This distinction between soma and germ track recalls Ascaris, where parts of chromosomes, and Sciara, where whole chromosomes, are lost in all somatic cells. But in Sorghum we know that the chromosomes which undergo 'diminution' are in fact dispensable not only in parts of the plant but also in parts of the species. More than half the population have none. Diminution in the individual and equilibrium in the population are therefore two properties of inert chromosomes related by their common dependence upon being useful without being indispensable[16].

This condition of usefulness brings us back again to the notion that they are not indeed inert but rather non-specific in their activity; that their different products do not take part in a series of specific reactions co-ordinated in time and space with those of different active genes, but rather take part indiscriminately in all gene and cell reactions. This character might be due either to their production of smaller types of protein, as suggested by Caspersson, or merely to the control they have been shown to exercise over the production of nucleic acid.

Whatever the means, the end result, an effect of heterochromatin on cell division, is shown by the behaviour of pollen grains containing inert chromosomes in Sorghum. The first pollen grain mitosis, which produces the vegetative and generative nuclei, is normally followed after a week by the division of the generative nucleus to give two sperms. Instead, the vegetative nucleus in pollen grains with extra chromosomes at once divides again and goes on dividing until it has produced four or five generative nuclei, and in so doing has killed the cell. The thick wall confines this growth within the grain and makes it an encapsulated tumour.

These morbid mitoses suggest that the activity of the inert chromosomes in healthy tissues will serve to stimulate nuclear and hence cell division. Further, that healthy growth will depend on a correct euchromatin-heterochromatin balance, morbid growth on an incorrect balance, perhaps in cancer on a difference in balance between different cells of the same tissue.

The control of the nucleic acid attachment of the heterochromatin itself becomes from this point of view of more than trivial interest. Certain plants and animals with the largest mitotic chromosomes have well-defined blocks of heterochromatin amounting to a quarter or even half of the whole bulk. When the nucleus is brought into mitosis at a low temperature, below 6° C., equally in plants such as Trillium[17], Fritillaria or Adoxa[18], or in the newt Triton[19], the heterochromatin is starved of its nucleic acid. The segments in question appear scarcely stained by the Feulgen reaction. It seems as though the supply of nucleic acid has been reduced and the heterochromatin has been unable to compete equally with the euchromatin for the reduced supply (Fig. 2, below).

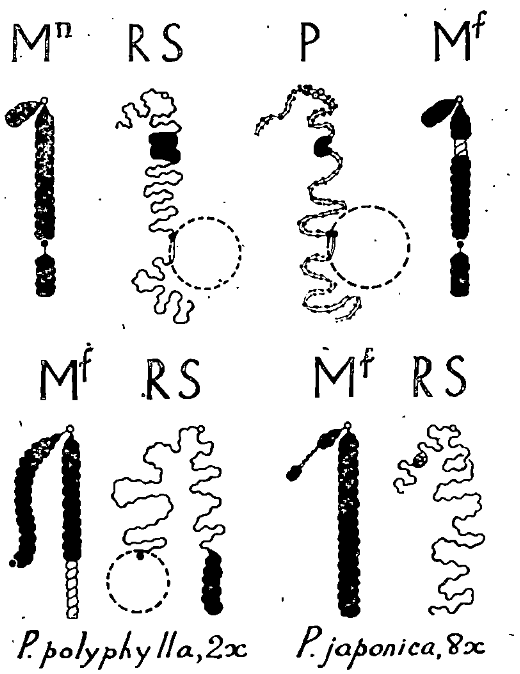

Fig. 2.

ABOVE: DIAGRAM SHOWING THE NUCLEOTIDE CYCLE OF A CHROMOSOME OF *Fritillaria pudica*. *P*, PAIRED AT PACHYTENE AND *Mf*, AT METAPHASE AFTER FREEZING. BELOW: INVERSION OF NUCLEOTIDE ATTACHMENT AS BETWEEN RESTING STAGE AND A CHILLED METAPHASE IN DIPLOID AND OCTOPLOID SPECIES OF PARIS. SPIRALIZATION OF HETEROCHROMATIN IS SUCCESSFUL IN *P. polyphylla*, UNSUCCESSFUL IN *P. japonica*.

This controlled starvation leads to derangement of two vital chromosome functions. First, the reproduction of the starved segments is hindered. Sister chromatids stick together, either at the ends or in the middle, and form bridges when they should separate at anaphase. This, when conditions other than temperature have happened to be abnormal, is a common source of chromosome breakage which in turn, by the way, must always lead to a change in heterochromatin balance[20]. Secondly, spiralization may be stopped and the heterochromatin appear as an entirely uncoiled thread at metaphase. This happens at meiosis in the male newt. Here the chromosomes have just emerged from a diffuse stage intercalated in the middle of the prophase and remarkable for having the heterochromatin uncharged, that is, for having no store of thymonucleotides. Similarly, it happens at mitosis in polyploid species of Paris and Trillium, which differ from diploids in having so small a stock of heterochromatin that again no thymonucleotides will be available within the nucleus (Fig. 2, below). Thus the nucleic acid attachment is necessary, not only as predicted for reproduction, but also for spiralization.

Conditions found in Nature advance the argument another step. In many animals of the heterozygous sex there is a large heterochromatic segment of the *X*-chromosome which is unpaired. In resting stages of the sperm mother cells and their antecedents this segment is strongly super-charged and there is no nucleolus. Apparently the transference of histones and exchange of nucleic acids surmised by Caspersson between heterochromatin and nucleolus has been blocked. During the prophase of meiosis this super-charging is strongest, and at the following metaphase a second remarkable property of the *X*-chromosome shows itself. Subject to variations in supply due both to genetic and to external conditions they are liable to fluctuate in their nucleic acid charge. They may be super-charged or sub-charged, or in the extreme case of the hamster Cricetus, they may be so little charged that they are unspiralized as in the experimental Triton[21]. Thus, like a lowering of the temperature, a suppression of the nucleolus can upset the regulation of the nucleic acid supply.

An adaptive effect of super-charging on reproduction is found in the Heteroptera. The normal pairing of the sex chromosomes is suppressed, and they divide at the first division instead of the second. Similarly, in many species of Drosophila there is a gene-complex 'sex-ratio' which exists in equilibrium in the population. Its effect is to increase the nucleic acid supply and therefore the charge on the heterochromatin at meiosis in the male. In consequence the division cycle of the *X* is advanced so far that it divides twice instead of once, and the *Y*-chromosome, immobilized by its heavy coat of nucleic acid, is lost in the cytoplasm. Hence the sperm all have *X* and the progeny are all female. This effect is reduced at higher temperatures so that up to six per cent of male offspring are produced. Evidently a causal sequence, temperature – nucleic acid charge – gene reproduction, is operative and can be used as part of the adaptive machinery of the species when it is combined with the usual high heterochromatic content of the sex chromosomes[22].

The imitation of natural abnormalities by experiment can take us further. Unfavourable conditions often produce a super-charging of the chromosomes. In maize a gene has this effect on the metaphase chromosomes, and an X-ray dose of 100 r. has the same effect. It is then found that the chromosomes are 'sticky'. What does this mean? When cold-treated chromosomes are X-rayed they show both stickiness and starvation. The charge on the heterochromatic segments remains less than that on the rest. They are thinner, but they are nevertheless coated with nucleic acid which stains deeply. It seems, then, that the stickiness is due to an excess of nucleic acid over the normal attachment and an excess with different physical properties[23].

The meaning of this effect becomes clearer when we realize that the X-rays act on the cell primarily by their effect on fibre formation: 50 r. will upset spindle development[23], but the germination of ripe pollen grains, a simple process not requiring fibre formation or even immediate nuclear control, is not disturbed by 80,000 r[24].

In this regard the distinction between fluid and fibrous elements, or at least surfaces, in the nucleus is important. The centromere, the nucleolus, the super-charged heterochromatin and the sticky chromosomes have a fluid surface. They run together. The normally charged chromosomes have a fibrous surface based on their fibrous framework. They stand apart. This difference between fluid and fibre would seem to depend on the polymerization of thymonucleic acid in contact with the chromosome. Here, again, there is a minor interlocking system of control, for while we saw that the nucleic acid charge controls the division of the centromere as well as of the whole thread of the sex chromosomes, the centromere itself often appears to act as the organizing centre for the charging of the chromosomes. At meiosis it then controls their pairing, which runs on a zip principle from the centromere to the two ends. In a word, the centromeres organize fibre formation both in the nucleus and on the mitotic spindle.

Thus we see a chain of reactions : the chromosome thread controls the polymerization of its thymonucleotide charge. This in turn controls the spiralization and, as would be expected, the reproduction of the thread with its genes. Hence the whole course of events can be controlled by temperature and other cell conditions as well as by the balance of heterochromatin and the organization of the nucleolus.

In this way the pattern of nuclear structure and organization is beginning to appear. But in answering some old questions we have, of course, raised far more new ones. Is the protein fibre of the chromosomes a single or a multiple chain ? Is a difference in multiplication or in charge responsible for differences in chromosome size ? Why have the prosthetic groups, which represent the genes and express themselves so clearly as chromomeres, active or inert, remained unidentified ? How does the nucleic acid attach itself to these groups and so control mating and reproduction (both limited to pairs) ? Is nucleic acid the agent of reproduction, or only of separation, of the main chain or of the prosthetic groups or of both ? If it controls spiralization, is it itself polymerized in a spiral with a limited number of stable positions ? How can the nucleic acid charge at prophase of meiosis be limited in quantity or arrangement so as to avoid reproduction and spiralization long enough to permit pairing ?

These and many other questions we can now attempt to deal with in a co-ordinated way. This we can do because at the same time that a new means of knowing the chemical structure and activity of the chromosomes and genes has been placed in our hands we also find ourselves provided with a variety of means of controlling this activity and modifying this structure ; with the instruments, in fact, for showing cell physiology and chromosome mechanics, no longer as opposite sides, but as interlocking parts of one system.

EDMOND HALLEY, 1656-1742

By DR. H. SPENCER JONES, F.R.S.
Astronomer Royal

ON January 14, 1742, died Edmond Halley, a remarkable man whose name is familiar to the public through the famous comet that is called after him. Born on October 29, 1656, in affluent circumstances, Halley took an early interest in astronomy. He went to St. Helena for two years, 1676–78, to observe the positions of bright southern stars, and while there observed the transit of Mercury of November 7, 1677, being the first person to observe both ingress and egress at the same transit. On his return, he published in 1679 the "Catalogus Stellarum Australium" ; in this he referred to the utility of observations of transits of the inferior planets for determining the solar parallax. Reverting to this subject in the *Philosophical Transactions* of 1694 and 1716, he proposed that the length of time taken by the planet to cross the sun's disk should be observed at a number of suitably selected stations ; from the differences in these times, the solar parallax can be inferred. The method has the advantage of not requiring elaborate instrumental equipment but suffers from the disadvantage that it requires the visibility of both entrance and exit at the same station. The method was widely used at the transits of Venus of 1761, 1769, 1874 and 1882.

Shortly after his return to England in 1678, Halley was elected a fellow of the then young Royal Society, of which in 1685 he became clerk and in 1713 one of the secretaries. In 1682 he made observations of the position of the bright comet that bears his name. It was probably this comet that turned Halley's attention to the consideration of the law of force under which an elliptic or parabolic orbit is described. He discovered in 1684 that for circular orbits with the sun in the centre the force for different orbits varies according to the inverse square of the distance. Being unable to solve the problem of the law of variation of the force for an elliptic orbit, he visited Newton in Cambridge in August 1684 to discuss the matter with him. He found to his surprise that Newton had already solved the problem and was able to supply the answer, but had mislaid his demonstration. Newton therefore worked out the proposition afresh and sent it in November to Halley, who made a further visit to Newton to encourage him to continue his researches. It was due to Halley's encouragement that the manuscript treatise, entitled "Philosophiæ Naturalis Principia Mathematica", which forms the first book of the "Principia", was presented to the Society in April 1686. The Society ordered that the book should be printed, but the state of the Society's finances at the time was such that it could not bear the expense. At the meeting of Council on June 2, 1686, it was accordingly resolved that the book be printed and "that E. Halley shall undertake the business of looking after it, and printing it at his own charge, which he engaged to do". Thus, as de Morgan remarked, Halley's "share in the production of the *Principia* entitles us to say that but for him, in all human probability, that work would not have been thought of, nor when thought of written, nor when written printed".

After Newton had demonstrated that the orbits of comets were sensibly parabolic and had devised a method for determining the elements of a comet's orbit, Halley collected all recorded observations of comets that had any claim to accuracy and computed the orbits of twenty-four comets. Among these were three that showed remarkable similarity: the comet of 1531, observed by Appian; that of 1607, observed by Kepler; and the comet of 1682, observed by Halley himself. Historical records of the appearances of comets in 1305, 1380 and 1456 confirmed his suspicions that these were all returns of the same comet. No method was then available for computing the perturbations due to the planets but, making an approximate estimate of the perturbing action of Jupiter, Halley concluded that the comet would be seen again about the end of 1758 or the beginning of 1759. "Wherefore", he remarked, "if it should return according to our prediction about the year 1758, candid posterity will not refuse to acknowledge that this was first discovered by an Englishman." Intense interest was taken in this prediction as the time for the return of the comet approached; it was a test question put by science to Nature. The discovery of the comet on Christmas Day, 1758, and its perihelion passage on March 12, 1759, was one of the most outstanding triumphs that Newton's theory had achieved.

In 1625 Kepler had found that the observed places of Jupiter and Saturn could not be reconciled with their accepted mean motions. The inequality in the motions of these planets was explained by Halley as the effect of their mutual attractions. A more puzzling phenomenon was discovered by Halley in 1695. By examining the records of ancient eclipses, he was led to the conclusion that there was an acceleration of the mean motion of the moon. This was amply confirmed after Halley's death, and many of the greatest mathematicians and astronomers endeavoured to find the explanation. In 1787 Laplace announced that the acceleration was the result of a gradual decrease in the eccentricity of the earth's orbit, produced by the action of the planets on the earth. In 1853, however, J. C. Adams found that the calculations of Laplace were incomplete and that the correct theoretical value of the secular acceleration of the moon's motion was only about half the observed value. The cause of the residual acceleration was not found until 1920, when the work of G. I. Taylor and H. Jeffreys proved that it was the result of a gradual slowing down of the rotation of the earth, produced by tidal dissipation of energy in shallow seas.

Another important discovery made by Halley was that of the proper-motions of the stars. In the *Philosophical Transactions* of 1718 he announced that Sirius, Aldebaran, Betelgeuse and Arcturus had changed their positions in the sky since the time of Ptolemy; the old idea that the stars were absolutely immovable with respect to each other was thereby disproved.

But Halley was not merely a great astronomer. He made important contributions to many other branches of natural philosophy. In 1688 he produced the first meteorological chart, showing the trade-winds over the oceans, based partly on his own observations. He was interested in the theory of the earth's magnetic field. King William III, being desirous that the variations of the compass should be observed in various parts of the Atlantic Ocean, for the benefit of navigation, gave Halley a commission as a post captain in the Royal Navy in command of the pink *Paramour*. The voyage lasted for two years, 1698–1700, reaching as far south as lat. 52° 30′ S. Numerous observations of the declination were made, from which a sea-chart for the Atlantic Ocean, showing the isogonals or lines of equal declination, was constructed. This chart was published in 1701 and was a valuable aid to navigation. The novel method that Halley devised for exhibiting the data is still used for magnetic charts. In 1702 he published a more extended chart, covering the whole world, which he based on all available observations. In 1701 he also carried out for the Admiralty an exact survey of the tides in the English Channel.

Halley's versatility is further indicated by his construction of the first mortality tables, thus beginning the science of life statistics.

In 1703 Halley was appointed Savilian professor of geometry at Oxford. His labours in his new position were in the neglected field of the remoter Greek geometry. He translated and edited an Arabic version of the lost work of Apollonius "De Sectione Rationis". In collaboration with David Gregory, he undertook an edition of Apollonius. But, in consequence of the sudden death of Gregory in 1708, when less than a quarter of the work had been accomplished, it was left to Halley to carry it through to completion. This edition, the first and, until the latter part of the last century, the only printed Greek text of Apollonius, was a tribute to Halley's industry and scholarship.

On the death of Flamsteed, the first Astronomer Royal, in 1719, Halley was selected in 1720 as his successor at the Royal Observatory, Greenwich, being then in the sixty-fourth year of his age. Flamsteed's instruments, the cost of which had been defrayed out of his own pocket, had been removed by his widow, who claimed them as her own property and succeeded in maintaining her claim against the objections of the Admiralty. The Royal Observatory had thus practically to begin again. Halley obtained a grant for new instruments and equipped the Observatory with a transit instrument and a mural quadrant by Graham. The chief work he did as Astronomer Royal was to make observations of the moon through an entire saros period of eighteen years, with the view of improving tables that he had published in 1719; these were intended to enable longitudes at sea to be determined by the method of lunar distances. It does not appear, however, that the revision of the tables was ever attempted. Though Halley had a more versatile and original mind than Flamsteed, as Astronomer Royal he achieved less, for he did not so fully appreciate those habits of minute attention that are necessary for the attainment of a high degree of accuracy in routine programmes of astronomical observation. The work for which his name will remain famous was completed before his appointment to Greenwich.

Astronomer, geometer, mathematician, physicist, geographer, practical seaman and navigator, scholar and critic—Halley filled all these roles with distinction. As de Morgan said, "Wherever Halley laid his hand, to do work cut out by himself, he left the mark of the most vigorous intellect, the soundest judgment, the most indomitable courage against difficulties." The name of Edmond Halley will always hold an honoured place in the history of English science.

CONFERENCE ON SCIENCE AND THE WAR EFFORT

IT is natural to compare the Conference organized by the Association of Scientific Workers on January 10 and 11 with that convened last October by the Division for the Social and International Relations of Science of the British Association. The difference was striking. Whereas the October Conference was concerned with post-war planning, this conference discussed in a practical way the immediate scientific and technical problems of the War itself. Even more noticeable was the difference in the type of person who, in general, attended and spoke. Here were gathered together in the main rank-and-file men of science fresh from their work in laboratories, factories and research institutions all over the country. They came not only with grievances and criticism (of which there were plenty), but with proposals for better co-ordination of research and better utilization of our technical personnel. However, the Conference was not dominated by youth. An encouraging feature was the support it received from distinguished men of science, although the amount of this support would not appear to have been commensurate with the importance of the topics discussed. These topics ranged from the training of technical personnel and the university education of scientific workers to the organization of maximum productive effort. In addition, there were important contributions on the subjects of food and agriculture, and building, housing and A.R.P.

Sir Daniel Hall, vice-president of the Association, who opened the Conference, emphasized that men of science must have regard to the actual machinery by which Government is carried on, otherwise their proposals would receive scant consideration. He stated for the consideration of the Conference that the real problem was for scientific workers and the Government itself to find the machinery which would ensure a proper method of using the expert. Captain L. F. Plugge, chairman of the Parliamentary and Scientific Committee, welcomed the Conference on behalf of his committee, and expressed the hope that his Committee would be informed of the matters discussed, so that they could be followed up. New methods in building worked out as a result of the war-time shortage of materials were described by Dr. R. Fitzmaurice, of the Building Research Station. Prof. J. B. S. Haldane pointed out that had many of the recommendations of the A.R.P. Co-ordinating Committee been adopted, not only would there have been an immense saving of life but also a saving of materials and money.

Sir John Orr treated nutrition from the point of view of its effect upon the efficiency of the worker, soldier and civilian. He pointed out that considerable increases in food production are necessary to provide a decent standard of health. Dr. H. M. Sinclair, of the Department of Biochemistry, Oxford, emphasized that the primary cause of malnutrition is poverty, with the secondary factors of ignorance and the decreased availability of familiar foodstuffs. Sir Daniel Hall outlined a post-war policy for agriculture. He characterized the policy of high prices as a policy of scarcity, and called for national ownership of our limited land area. Sir John Russell, Prof. H. D. Kay, Prof. F. G. Gregory, and Dr. A. Walton contributed to an extensive discussion. Prof. J. A. Carroll called for a co-ordination between school and university, and for an inquiry by such a body as the Association of Scientific Workers into the scope and content of courses. Mr. J. A. Lauwerys discussed elementary technical education, and suggested that a closer contact between schools and the industrial world would be valuable. Both sessions on education were marked by the practical detail of the discussions.

The two sessions on January 11 were devoted to the place of the industrial and Governmental scientific worker in the war effort. Prof. W. Wardlaw, and Mr. F. M. H. Markham, of the Central Register, spoke and answered criticisms of the working of the Register. Mr. E. D. Swann, of the executive committee of the Association of Scientific Workers, outlined the Association's case for a select committee to investigate the whole question of the utilization of scientific personnel and for the production executive to appoint a technical personnel committee. Prof. H. Levy asked for a place for scientific men in the commands of the fighting forces, while Mr. F. Morgan, an operational research scientist attached to an R.A.F. Command, outlined the vital work which he and his colleagues are doing, and made suggestions for its improvement. Mr. Halse, of the Industrial Committee of the Association, gave numerous examples of inefficiency in the actual working of industry. Mrs. P. Clarke spoke of the low rates of pay of explosives chemists, which compare unfavourably with those received by unskilled personnel. Drs. Garland, Stanford and McClean made out an impressive case for better medical services in industry, and the consequent effect on production.

Scientific workers from a variety of undertakings took part in the discussions. The unanimous opinion seemed to be that production is being handicapped by lack of scientific training, mismanagement and inefficiency in high places, and through the spirit of peace-time competition between firms. Lack of contact between the Services and scientific workers was emphasized. Mr. J. A. Henley summed up this part of the conference while Prof. J. D. Bernal dealt with the proceedings as a whole. He stated that if the whole truth could be told, the situation would seem to be even worse than that described by the speakers from their first-hand experience. He said that attempts by men of science to better the situation would meet with opposition from industry and from the Government. In his view, the opposition to scientific workers in the last few months is equivalent to sabotage and perhaps something rather stronger. He underlined the need for speed in view of the urgency of the situation.

Thus ended one of the most significant gatherings of British scientific workers held during the War. It ended on a note of action, as representations by the Association are to be made to the Ministries of Labour and of Supply as a direct result of it. It is to be hoped that the facts which came to light will be most seriously considered by these Ministries.

OBITUARIES

Dr. H. Eltringham, F.R.S.

Harry Eltringham, who died on November 26, was the eldest son of J. T. Eltringham of South Shields, and was born in 1873. Educated at South Shields High School, and then at Durham School, he was destined for a business career with science as a background. His natural leanings to science owed much in his youth to his father's encouragement. He entered Trinity College, Cambridge, in 1891, and took an honours degree in natural science, after which he spent a year in the engineering 'shops' studying mechanical drawing and practical work. His father's shipbuilding business claimed him for some years after, but in 1908 he retired, and devoted himself to the study of insect mimicry, which had already attracted his attention.

Eltringham went to Oxford to study under Prof. E. B. Poulton, and in 1910 his fine book, "African Mimetic Butterflies", profusely illustrated with plates from his own coloured drawings, was published by the Clarendon Press. The intricacies of mimicry among Acraeine butterflies attracted him, and in 1912 he wrote a monograph on the African species of Acraea, thoroughly revising this difficult genus and describing new forms and species. Later, he treated similarly the neotropical genus Heliconius in a superbly illustrated paper (1916), discussing the specific and mimetic relationships.

Taxonomic studies necessitate anatomical research, and Eltringham was led to the histological studies for which he will be chiefly remembered. Field naturalists in Africa had described the habits in courtship of Amauris butterflies, which seemed to depend upon the charging of an abdominal brush with secretion from special areas on the wings, and dissemination of this presumed scent to the female by protrusion of the brush. Eltringham in 1913 described fully the histology of the parts in two species, following this account with a further paper in 1915. Similar structures in the allied Oriental genus Euploea were described in 1935 in a communication to the Royal Society, to which he had been elected in 1930.

These studies led Eltringham to consider other specialized structures, and numerous papers on glandular, tympanic, and brush-organs, and special sense-organs of unknown function in Lepidoptera and other insects came frequently from his pen at Oxford and, after 1935, from Stroud, where he equipped his own laboratory. One of the best known, entitled "Butterfly Vision", described with very finely executed drawings the minute anatomy of the compound eye. A microphotograph of Prof. Poulton, taken through the eye of a glow-worm, added interest to the discussion of theories of insect vision. One of the latest studies, in 1936, dealt with the eyes of tsetse flies. Eltringham's greatest histological successes were the description in 1920 of the apparatus, apparently for producing scent, concealed in a protrusible pouch in the back of the head of Hydroptila, a caddis-fly only a few millimetres long, and the account in 1933 of the anatomy of tarsal sense organs in Lepidoptera; also the account, published in 1928 by the Royal Society, of the silk-producing glands in the front tarsi of the small Empid fly Hilara, the amazing courtship of which had been watched by A. H. Hamm.

Eltringham's aptitude for drawing was enhanced by his engineering training: he despised no mechanical aid to producing accurate representations, and his illustrations demonstrate clearly what he describes. Similarly, his ingenuity enabled him to devise and make a vertical projection apparatus for drawing microscopical preparations, and a camera for very low-power microphotography. Other apparatus, such as a rocking stage for the microscopical examination of insects, keeping them always in focus, and an improved air pump for laboratory use, are on the market. His book on "Histological and Illustrative Methods for Entomologists" (Oxford, 1930) was the outcome of his own experience.

Eltringham also wrote in 1923 an engaging little book, "Butterfly Lore", dealing with the economy of a butterfly from egg to adult, and, in 1933, "The Senses of Insects". His last published work was "The Mind of the Bees" (1936), translated from the French of Julien Françon. The majority of his papers, numbering about seventy, were published by the Royal Entomological Society of London, of which he was president in 1931–32.

Eltringham was no mean athlete: he secured his Trial Eights cap at Cambridge and was well known as a skater in Switzerland, where he was twice among the judges at the English championships: he held the Gold Badge of the 'Bear' skating club. He was a friendly man but surprisingly self-contained: he had a keen appreciation of beauty in music and a colourful garden. He left Oxford to help his sister tend their mother at Stroud in her failing health, and after her death lived there. He was unmarried.

G. D. Hale Carpenter.

Mrs. Hertz

The death occurred on December 29 of Mrs. Hertz, widow of Dr. Heinrich Hertz, whose name will always be associated with the beginnings of radio communication.

Mrs. Hertz came to England in 1936, at the age of seventy as, although 'Aryan' herself, her husband's Jewish ancestry made it undesirable for her to continue to live in Germany. Admirers of her husband's work and the Marconi Company made it possible for her to live in England, and her two daughters also. The elder daughter had had a large medical practice among children at Bonn, where she lived with her mother; the younger did distinguished work in psychological zoology in Berlin, which she has continued at Cambridge.

Mrs. Hertz was a native of Karlsruhe, in Baden. A few years ago the late Pope made her a donation of £200 in acknowledgment of a gift of one of her husband's manuscripts to the Vatican Library. Another manuscript Mrs. Hertz generously gave to the library of Trinity College, in commemoration of Sir J. J. Thomson's eightieth birthday.

Joan Thomson.

We regret to announce the following deaths:

Mr. J. P. d'Albuquerque, formerly director of science and agriculture, Barbados, on December 20, aged seventy-five.

Major Edwin C. Eckel, chief geologist, since 1933, of the Tennessee Valley Authority, on November 22, aged sixty-seven.

Prof. D. D. Jackson, formerly professor of chemical engineering in Columbia University, aged seventy-one.

Prof. R. D. Rudolf, emeritus professor of therapeutics in the University of Toronto, on November 2

NEWS and VIEWS

Scientific Societies and Post-War Problems

AFTER winning the War of 1914, the Allies lost the peace because of the inability of statesmen and public opinion to understand the dependence of national security on world order and the dependence of world order upon truly workable international relations. After the defeat of Nazism, the mistakes of the last twenty-two years must be avoided by the victorious nations. Hitler has a 'new order' for Europe which is apparently an old-fashioned Roman peace. Aside from the very general Atlantic Charter signed by President Roosevelt and Mr. Churchill, no definite peace plans have been advanced by the Allies, although many groups both in and out of Government circles are working on aspects of the problem. The American Academy of Arts and Sciences is devoting its regular monthly meetings, November until May, to the subject of "Analysis of Post-War Problems and Procedures". The Academy, which has approximately eight hundred members elected from a wide variety of professional fields, includes men who are competent to give considered views on the natural and social sciences and in engineering and affairs; and the meetings are being held on the second Wednesday of the month at its Boston house under the chairmanship of Dr. Harlow Shapley, president of the Academy. On the Monday following, there is a forum directed by leaders chosen to discuss matters raised by the preceding Wednesday evening's speaker.

Prof. A. N. Whitehead, emeritus professor of philosophy at Harvard University, opened the series in November with a paper entitled, "Statesmanship and Specialized Learning"; Samuel Cross, J. Seelye Bixler and Hans Kelsen, also of Harvard, led the forum following this communication. The meeting on December 10 was concerned with problems of communication and transportation in a post-war world. Igor I. Sikorsky, engineering manager of United Aircraft Manufacturing Corporation, spoke "On the Air Transportation of the Future". Walter S. Lemmon, president of the World Wide-Broadcasting Foundation, spoke on "Radio as a New Force in the Post-War World". The forum on December 15 was led by Douglas H. Schneider, programme manager of Station WRUL, and Joseph S. Newell, professor of aeronautical structural engineering at the Massachusetts Institute of Technology. The January 14 meeting is being addressed by Zechariah Chafee, jun., Langdell professor of law at Harvard University, on the subject of "International Utopias". Among the topics for later meetings will be considerations of sources and availability of raw materials in a post-war world and discussions as to how the social sciences may best be utilized to implement the ideals of democracy.

Aircraft Defence against Barrage Balloon Cables

PHOTOGRAPHS of German Heinkel III aircraft, shot down recently, reveal the fact that these machines are fitted with a balloon cable fender not very different from designs tried by both sides during the latter part of the War of 1914–18. It consists of a metal rail, V-shaped in plan form, attached to the wing tips with the point of the V carried on a pylon forward of the nose of the machine. Thus, when meeting a cable it is fended off by being slipped round the wing tip. The weight and drag of the device is considerable, and has an appreciable effect upon the performance. British machines now use a row of small cable cutters along the leading edge of the wings. If the cable strikes between the cutters it slips along until it reaches the nearest one. This device is considered to be better, in that it releases the balloon, and clears the way for any following machines. The weight is less than that of the German fenders, although the comparative aerodynamic effects are not certain. The problem of ice formation on either type is likely to be serious, and in this case the British design, placing the cutters in the wing, which is probably already fitted with de-icing devices, is less likely to accumulate serious ice formations than the German exterior structure.

Czech Medical Work in Britain

SHORTLY after the Czechoslovak Government was formed in London, a Department of Public Health was set up under its Ministry of Social Welfare to meet the needs of Czechs in Britain and to prepare for the onerous duties that await them on the liberation of their country. There are about 250 qualified Czech medical men and women in Great Britain. Many are serving with Czechoslovak army units, others are with the merchant navy and some (in co-operation with the Red Cross) are concerned with the welfare of their countrymen resident in Britain. There are clinics and wards in certain hospitals at their disposal and a Czechoslovak Medical Association in Great Britain has been formed to hold regular scientific meetings. Through the Czechoslovak Research Institute, it has just issued the first number of a *Bulletin* in English, to which Lord Horder has contributed the foreword. Lord Horder points out that medicine knows no racial distinctions and recognizes no geographical boundaries. Both nations (Czech and British) are allies and friends opposing the medievalism into which Nazi Germany would thrust all man's endeavours. The paralysis of the advance of medicine which war induces is one of the most serious effects of the crime committed by Germany against civilization, yet Czech medical men are keeping alight the flame of learning and of healing so that, when victory comes, medicine will shine again in the new home they will provide for her.

The *Bulletin* contains several informative articles on current Czech medical work. Before it was overrun by the Nazis, the country had an efficient and well-organized medical service with one practitioner to every 1,500 inhabitants. There were 548 hospitals with 90,000 beds, while all classes of the community could take advantage of the country's unique spa and sanatoria facilities. After the War ends, Czechoslovakia will be in urgent need of medical men, and it is important that Czech medical students now in Britain should complete their studies in readiness for future duties in the homeland, where there is no rising generation of doctors since the Nazis have closed all the medical and scientific faculties of the Universities of Prague and Brno.

New Mexican Observatory

A NEW national observatory which will house a 24–30 in. Schmidt photographic telescope, claimed to be the most powerful in the tropics, is being built in Mexico. Other equipment will include a 12-in. reflector for visual observations and two or three cameras of the Ross type with apertures of 3–5 inches.

The observatory will be situated on a hill ten miles south of the city of Puebla, which is eighty miles east of Mexico City. This is a very favourable location in the southern hemisphere for observation. The latitude of the observatory is 19° N., which means that the sky can be seen to within 19° of the south celestial pole. The site is nearly eight thousand feet above sea-level. The work of the observatory will be closely linked with that of the Harvard College Observatory and of the Mexican Observatory at Tacubaya. It will consist largely of observations of southern variables and of star counts, colours, magnitudes and spectra for the southern hemisphere. The director of the observatory will be Mr. L. E. Erro, assisted by Dr. Carlos Graef, both of whom have already spent a year working at Harvard College Observatory.

Post-War Zoos

THE forty-first Bulletin of the North of England Zoological Society deals with the increasing difficulties facing societies which will have to maintain zoological collections during 1942, and makes a plea for public recognition of the zoological garden on the same standing as the art gallery and museum. The Society's zoo at Chester, like other collections at Dudley and Maidstone, saw a considerable increase in attendance in 1941 compared with the disastrous figures in 1940—Maidstone had about 40 per cent of normal pre-war years—and it is planned to invest money for post-war construction plans. "Not only in this country, but one might say all over the world, the problems of preserving the zoological collections will become more and more difficult as the war progresses from stage to stage" it is noted, adding, "It is very unfortunate that in the past both museums and zoos have suffered from a certain amount of apathy from both the government and the local authorities with the inevitable result that their development has been retarded. Many zoological societies have had to introduce various methods to raise money which most of them would like to have left entirely alone, but the necessity of raising funds left them no alternative. In the post-war period it is likely that art galleries and museums will receive more financial support from government and local authorities, but I am afraid that for some time to come zoological gardens will have to depend upon their pre-war sources of income." Among the post-war zoo ideas are a greater use of open spaces to display the animals to a better advantage, using ditches instead of iron bars and railings, to improve the labelling of exhibits instead of relying upon commercialized guide-books to impart the necessary information to the novice visitor, and more use of zoos by schools with the establishment of zoo lecture halls. The difficulties facing such schemes and how they might be overcome are dealt with.

The Birds of Leicestershire

THE Leicester Literary and Philosophical Society has formed an Ornithological Society for Leicestershire and Rutland, which is compiling a report on past and present field records, to be issued in 1942 as a preliminary to bringing up to date Montagu Browne's 1889 "Fauna of Leicestershire". A meeting in Leicester Museum last September decided to form an Ornithological Society, as a sub-section of the Leicester Literary and Philosophical Society, to meet monthly, Mr. F. Brady being elected chairman and Mr. A. E. Jolley secretary. A duplicated December bulletin, just issued, records the little owl, kestrel, partridge, red-legged partridge and a flight of grey geese within Leicester City bounds, and at the sewage farm a flock of tree sparrows, while a pectoral sandpiper is reported from Northampton Sewage Farm. At a large starling roost at March Covert, near Lockington, the ground was found to be littered with rubber bands believed to have been swallowed by the birds and later either vomited or passed in their excreta. They varied from fruit bottle to tobacco tin bands. Similar instances of this type have been recorded elsewhere with arctic terns, gulls and rooks, and it is probable that the birds mistake them for food, afterwards ejecting them as undigestible. At the flooded Wanlip osier beds, teal, pochard, shoveler and wigeon have been observed among the duck, as well as snipe, curlew and a peregrine. A sheldrake is recorded inland from the River Sence near Kilby Bridge. Although only opened in 1941 the Eye Valley Reservoir has already proved an important bird haunt.

Health of Scotland

ACCORDING to the report recently issued by the Department of Health for Scotland for the eighteen months January 1939 to June 1941, the health of that country in 1939 reached a level never attained before. The severe winter of 1940–41, however, was responsible for the deterioration in the first quarter of 1941 when the infantile mortality rose to 109. In 1939, 7,176 cases of tuberculosis with 3,526 deaths were reported, and in 1940, 7,670 and 4,003 respectively, while in the first half of 1941 the figures were 4,300 and 2,300. With the exception of tuberculosis, the War has so far not had much influence upon infectious diseases, unless the increased incidence of cerebrospinal fever be attributed to war conditions. There was an increase in diphtheria of about 50 per cent in 1940 over 1939, but in 1941 the incidence declined; about 440,000 children of school age and under, or approximately 40 per cent of the child population, have been immunized.

Rotation of the Milky Way

A SUMMARY of the most up-to-date knowledge of the galaxy is provided by an article by Frank K. Edmondson in the *Telescope* of September–October. A short historical outline of the subject is given, commencing with Glydén's discovery in 1871 of the galactic rotation effect in stellar proper motions, and dealing finally with recent research on the constancy of orbital velocity over a range of about 5,000–15,000 parsecs from the galactic centre. The explanation of this constancy in the rotational velocity is that the distribution of stars in the galaxy lies between high concentration towards the centre and uniform distribution. It has been estimated that the number of stars per unit volume near the centre must be a hundred times that in the neighbourhood of the sun. If this is correct, the sky should appear very brilliant in the direction of the galactic centre. As it does not do so, it is believed that huge clouds of dark interstellar matter partially conceal the centre from our view. For this reason the mysteries of that massive nucleus which lies behind the interstellar veil can be penetrated only through the assistance rendered by the study of star motions.

Electric Discharge Lamps

The War has forcibly directed attention to artificial lighting both indoors and out of doors. Black-out conditions in towns with their mentally depressing effects, their restrictions on social intercourse and their responsibility for more street accidents have emphasized man's dependence upon electric lighting. Indoors, particularly in modern factories which, like Hardwick Hall, are more glass than wall, the same black-out conditions have resulted in the continual use of artificial light even in the day-time. Specially welcome, therefore, is the interesting account of "Electric Discharge Lamps", written by V. J. Francis and H. G. Jenkins, recently published from the Research Laboratories of the General Electric Company in England. In about sixty pages an excellent technical account is given of "Osira" and "Osram" fluorescent tubes and their operating equipment. The many illustrations include spectrograms and oscillograms obtained from the tubes in operation. The story of the development of the tubes is an excellent illustration of the application of advanced academic physics in industry, and peace-time may well see the discharge lamp, historically the earlier, replacing the heated filament bulb.

Malayan Wild-life

Referring to the notes on Malayan wild-life in Nature of January 3, p. 17, Mr. F. F. Laidlaw writes: "the orang outan does not occur in the Peninsula, though it is of course found in Sumatra. The Malayan wild cattle is scarcely a bison, its native name should read sĕladăng, and the Malay name for the flying fox is kluăng. The common rhinoceros, now I believe preserved, was hunted for its horn, not for ivory, and the tusks of the Malayan elephant are usually too small to be of much value. It was hunted partly as a nuisance, and partly because it was an elephant! There is a likelihood of some confusion in the use of the term Malayan, meaning 'of the Malay Peninsula', opposed to Malaysian, which refers to the Peninsula *plus* the great islands, Sumatra, Java, and Borneo. For this latter concept 'Sondaic' might be better. 'Sundaland' is, I believe, used to denote all the lands of the Sunda shelf".

Synthetic Rubber in the United States

It is announced that the leading rubber, oil and chemical companies of the United States have agreed to pool their patents and technical processes to construct plants with a capacity of 400,000 tons of synthetic rubber a year. The undertaking is expected to cost about £100,000,000.

Announcements

The Bessemer Gold Medal of the Iron and Steel Institute for 1942 has been awarded to Mr. Eugene G. Grace, president of the Bethlehem Steel Company, in recognition of his valuable services to the iron and steel industries and in appreciation of all he has done to foster technical, scientific and industrial collaboration between the industries in Great Britain and the United States.

The Committee of the Athenæum has elected the following gentlemen under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature or the arts, or for their public services: The Right Hon. Sir John Anderson, Lord President of the Council; Admiral of the Fleet Sir Dudley Pound, First Sea Lord of the Admiralty; General Sir Archibald Wavell, Supreme Commander, South-West Pacific Area.

Father W. McEntegart, Heythrop College, Chipping Norton, Oxford, has written referring to Prof. W. G. de Burgh's review of Dr. Osborne Greenwood's "Christianity and the Mechanists" in Nature of November 29, p. 637, where the following passage occurs: "Even Aquinas held that reason could not disprove the eternity of the material world and that the belief in Creation could be authorized only by revelation". Father McEntegart points out, and Prof. de Burgh concurs, that the words "in time" should have been inserted after the word "Creation".

Dr. G. F. Herbert Smith, British Museum (Natural History), London, S.W.7, writing in connexion with the article "Nature Preservation and National Life" in Nature of Jan. 3, p. 1, states that the Conference of the Society for the Promotion of Nature Reserves, a memorandum of which is referred to, remains in being, and correspondence for it should be addressed to him.

Sir Arthur Hill, former director of the Royal Botanic Gardens, Kew, who died on November 3, left £93,379 (net personalty £92,653). He bequeathed £1,500 to the chapel fund of King's College, Cambridge, to provide carved statues in wood, a small statue of Henry VI, a silver tankard dated 1686, and his Dutch tiles to King's College; £200 to the supplementary expenses fund of King's College, and to a fellow of the College his doctor of science gown and hood; certain silver and other articles to the Archæological Museum of the University of Cambridge; £1,000 to the Bentham-Moxon Trustees of the Royal Botanic Gardens, his diaries of various journeys to the library of the Royal Botanic Gardens, and £500 to Kew Guild; his great Bible of Henry VIII to the Vaughan Library, Harrow School; £1,000 to the Royal Society; other bequests chiefly to religious bodies, and, after personal bequests, the residue as to one-eighth to King's College, Cambridge, and one-eighth to Marlborough College.

The Medical Research Council invites applications from medically qualified women for a studentship for training in methods of experimental psychology; preference will be given to candidates who have had some special training in physiology or neurology, or who have already had some experience in the use of research methods. The studentship will be tenable for six months during which the holder will receive training under the direction of Prof. F. C. Bartlett at Cambridge. Payment will be at the rate of £350 per annum, and the student will be expected to give her whole time to the work. The award will be made with the view of possible opportunities for research into problems arising during the War, either in the services or in industry, but no definite promise of employment after the expiry of the studentship can be given. Applications should be sent to the Secretary, Medical Research Council, c/o London School of Hygiene, Keppel Street, London, W.C.1, by February 9.

Colour Measurement

MR. J. W. PERRY's letter on colour measurement[1] may lead to misconceptions of the nature and status of the C.I.E. colorimetric system by colour workers who have not paid particular attention to the principles of colour measurement. In stating that the numerical colour specification $\chi_{\text{C.I.E.}}$ refers to (*a*) a normal observer and (*b*) normal observing conditions, including (*c*) a field of direct observation of 2°, Perry confuses the colorimetric standard with the procedure recommended for general direct colorimetry.

The 'standard observer' is a set of tables defining what is to be understood physically by colour, and has been adopted internationally for technical and commercial purposes. There is much evidence that this standard has proved satisfactory for a large range of such applications, and we know of none where it has been definitely found unsatisfactory. But whether the present tables are satisfactory or not, they are not restricted in their application to a given field size or field brightness or pupillary aperture or otherwise.

When measurements are made by the indirect spectrophotometric method, it is clear that these factors are irrelevant. Difference in colour merely means difference in $\chi_{\text{C.I.E.}}$, and can be specified to any accuracy attainable by spectrophotometry. Perry appears to think that, owing to the procedure adopted in the experiments on which the standard system was based, there exists a possibility of error in $\chi_{\text{C.I.E.}}$ values. But there is no possibility of error in what is by definition the standard, neither is there any tolerance. The definition is exact and unambiguous. The original measurements of Guild and Wright provided evidence that a standard based on their results would probably prove generally acceptable; once the tables based on these measurements were adopted as a standard, it became irrelevant whether they represented the visual properties of the groups of observers who contributed to the results with a high or a low degree of accuracy, and whether they were obtained with a large or a small field of view. There were in fact important reasons for choosing particular conditions, but it is unnecessary to discuss them here.

The recommendations for using particular conditions in general direct colorimetry were intended to guide a real observer in his efforts to obtain measurements likely to be in satisfactory agreement with the standard observer. When very small colour differences are to be measured, it is known that different conditions of observation should be adopted. It is possible that experience in these or other measurements may show that amendments should be made in the present standards to meet the increasing requirements of technical colorimetry. But any changes will be changes of detail and not of form. No new quantity χ_N, as proposed by Perry, involving a new physical concept, is involved in either differential or absolute colorimetry with large fields. The regional variation of retinal properties is formally irrelevant to appearances in an extended field. A physically uniform field will appear uniform in colour and brightness despite retinal variations, and colour matches with such fields will result in trichromatic equations of the same form as those obtained with a uniform field of small size. The results may differ numerically but not otherwise. In both cases the numerical differences from the C.I.E. values arise from departures of the colour vision of the real observer from those defined as the standard, that is, they are to be regarded as personal errors. It is well, however, to remember that it is only advantageous to use large fields for visual colorimetry when two specimens closely alike in spectral constitution as well as in colour are to be compared; the perception of a match or of small departures from a match is then very little affected by the observer's peculiarities of vision. In these circumstances all but extremely abnormal observers will obtain results agreeing with the standard to the limits of discrimination. Thus where a large field enables greater precision to be attained usefully, any consequent tendency for colour vision to depart from the standard becomes relatively unimportant.

We believe that Perry's difficulties about the standard observer are not real. Data of this type are formally necessary and sufficient for every colorimetric problem. If modification in the standard should ultimately be found desirable in the light of accumulated experience, it will be found a purely practical matter involving no change of principle. We can see no useful purpose that would be served by the philosophical inquiry desired but, to our minds, only obscurely indicated by Perry.

MR. J. W. PERRY's remarks[1] directing attention to the difference between the colorimetric concepts which he calls $\chi_{\text{C.I.E.}}$ and χ_N are opportune. As he points out, there is at present no real justification for applying the results of measurements made under the original standard C.I.E. conditions to problems involving other conditions of observation, and if nevertheless we do so, we must clearly realize that this procedure is at best a makeshift pending the publication of more detailed information. There is a need for fundamental research on the whole subject of the colorimetry of wide field systems.

The present position of colorimetry in the paper, printing and printing ink industry (and, I believe, several other industries) is this. If I have a sheet of paper which I have found by measurement to have colour *A*, it should be sufficient for me to order paper of colour *A* from the maker in the moral certainty that the paper, when it arrived, would match my sheet within commercial limits of tolerance; there should be no need for interchange of samples. Unfortunately, this is at present not so. Even if the paper mill and I both have visual colorimeters and they are used by experienced observers, it still does not follow that when the mill and I get identical colorimetric readings, that experimental making and sample will necessarily be a good commercial match. Of course, they may be so, and in any event they will not be *widely* different; but one cannot *guarantee* a match.

The trouble lies, of course, not in any fault in the design of our instruments, nor in a breakdown in the C.I.E. system, but in the fact that in practice the sheets are compared under conditions different from those laid down in the C.I.E. specification—conditions under which the eye is more sensitive. Further, I have taken as my example a favourable case ; but in industry the trouble is often aggravated by the use of 'colorimeters' of poor design and performance, constructed by works technicians with little knowledge of the principles of colorimetry. Now the 'practical man' in the trade tends to regard all instruments with suspicion, often, let us admit, with some justification ; and when colorimeters give the same readings when his own eyes tell him that the samples he is comparing differ appreciably in colour, no matter what the true cause of the discrepancy may be, he tends to lose faith in colorimetry altogether. This is regrettable, because if an improved method becomes available later—one which will be of real assistance to him—he will probably take no interest in it, saying that he has been 'caught' too often before. It therefore behoves one to be careful in introducing new instruments into industry.

Fortunately, as Perry points out, in many cases the papermaker would be quite happy if he had agreed colour standards to which to work, and a means of determining how far and in what directions the colours of actual makings of paper departed from these standards. What he really needs is a means of making sure that his own substandards do actually match the agreed standards, and a means of checking at convenient intervals the amount of discoloration of these substandards which may have occurred through ageing or chemical changes. This can be done conveniently and accurately by spectrophotometry, and it need not be done by the papermaker himself. The departures of different batches of papers from the agreed standards can then be studied over a limited region of the colorimetric field by means of a differential colorimeter of high sensitivity and precision, but only moderately high absolute accuracy. Photo-electric colorimeters which satisfy these conditions reasonably well are already available commercially. Until the fundamental work is done that Perry suggests, this procedure offers the best practical solution to the problem.

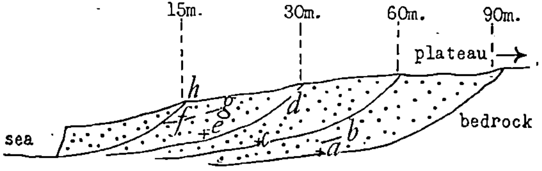
Pleistocene Raised Beaches on the West Coast of Morocco

ON the invitation of the Service of Antiquities I recently spent seventeen days in Morocco, studying the very important discoveries made by R. Neuville and A. Ruhlmann in the neighbourhood of Casablanca and Rabat.

The result of their work may be summarized as follows. The coastal deposits in this region testify to four separate marine transgressions during the Pleistocene, each followed by a period of retreat. The high sea-levels have left beaches at +90 m., +60 m., +30 m., and +15 m., corresponding to the Sicilian, Milazzian, Tyrrhenian and Monastirian beaches of Depéret. On each of these rests a complex of sub-aerial deposits—consolidated dunes, freshwater limestones, red clays—formed during the succeeding period of low sea-level. The whole series of beaches and sub-aerial beds forms a complete section of overlapping layers, as shown in the accompanying diagram.



DIAGRAMMATIC SECTION OF RAISED BEACHES AND SUB-AERIAL DEPOSITS IN THE NEIGHBOURHOOD OF CASABLANCA.

Up to the present the oldest known human industry in this region had been found in and on the 30 m.-beach, and was described as "Chellean". The work carried out by Neuville and Ruhlmann in the quarry of Abd-er-Rahman, near Casablanca, now gives a much more complete picture. Immediately overlying the 90 m.-beach (*A*) they found an extensive workshop of large heavy quartzite and sandstone flakes of Clactonian type roughly worked into bifaces, usually trihedral in section. The majority were unabraded, but a few were very slightly rolled, suggesting that the falling sea had occasionally returned to the level of the workshop. The accompanying fauna included hippopotamus and rhinoceros. The beach itself yielded shells of Acanthina (to-day found on the coast of Chile). The deposit containing the implements and bones was so hard that it had to be broken up with dynamite. In the overlying sub-aerial bed (*B*) was a horizon which yielded a few untypical flakes, and on the surface of the 60 m.-beach (*C*) similar flakes were found, again in small numbers.

CORRELATION TABLE

Mediterranean Beaches	Alpine Glaciations	Industries
90 m. (Sicilian) Beach	pre-Günz	Abbevillian Clactonian
Sub-aerial deposits	Günz	Untypical flakes
60 m. (Milazzian) Beach	Günz-Mindel	Untypical flakes
Sub-aerial deposits	Mindel	—
30 m. (Tyrrhenian) Beach	Mindel-Riss	Acheulean
Sub-aerial deposits	Riss	Acheulean
15 m. (Monastirian) Beach	Riss-Würm	Micoquian Mousterian
Sub-aerial deposits	Würm	Aterian

Overlying the 60 m.-beach are consolidated dunes, in which caves have been excavated by the sea which formed the 30 m.-beach. The floors of these hollows are covered with contemporary beach material, overlain by sub-aerial clays containing animal bones, and at the contact of the two types of deposit were found bifaces of Acheulean type.

The 30 m.-beach thus fragmentarily preserved is better developed in the neighbouring quarry of El Hank, where it yielded a large Murex, which replaces the Acanthina at this level, and the industry formerly described as "Chellean". I have studied the material from this level in the collection of M. Antoine, and find that it includes two distinct industries : (1) Abbevillian (Chellean), with bifaces made on pebbles and heavily rolled ; this is presumably derived from an older deposit broken up by the Tyrrhenian sea. (2) Acheulean, with typical and beautiful bifaces, some slightly rolled, but the majority unabraded. This must date from the end of the 30 m.-beach and immediately after, as in the caves at Abd-er-Rahman. Acheulean implements were also found in two dune deposits and a freshwater limestone overlying the 30 m.-beach (*F* and *G*).

The last marine deposit is the 15 m.-beach, and the history of an earlier stage is here repeated, for the Monastirian sea excavated caves in the consolidated dunes of the preceding period of emergence, and these contain sub-aerial deposits which have yielded an Aterian industry. Earlier than this, however, though slightly later than the 15 m.-beach, is a layer of red earth (*H*), which covers the sub-aerial deposits *F* and *G*, but does not belong to the same complex. This yielded Micoquian bifaces and a kind of rough Mousterian.

H. Breuil.

Change of Pelage in the Stoat *Mustela erminea* L.

The pelage change in captive stoats has been studied over a period of five years. The animals were caught at Ashton Wold, Peterborough, Northants, when only a few days old and hand-reared[1]. In this district the stoat normally remains brown throughout the year, although from time to time specimens are taken which show partial whitening in the winter.

Exposure to cold induced a colour change in three out of five stoats. In this particular experiment there was no artificial curtailment of the hours of daylight and no special feeding. The observations made may be briefly summarized as follows :

(1) The winter pelage may be white or brown.

(2) Captive stoats have two moults. This confirms Schwalbe's[2] observations made on wild specimens. The autumn moult occurs in late November, and the spring moult in February. The winter coat is thus carried for only three or four months. Examination of various skins shows that in northern districts the winter coat is carried for a much longer period.

(3) The date at which the autumn moult commences is generally regular, and unaffected by the temperature prior to the commencement of the moult, but the time taken for the moult to be completed is directly affected by the existing temperature. If it is low the entire moult and colour change can be effected in seventy hours. The extraordinary rapidity of the growth of the ingrowing winter coat has been demonstrated by shaving off portions of hair at this period. If the temperature is high, the moult may be spread over 10–20 days.

(4) Stoats from the same litter show great individual variation with regard to the change in colour. Exposed to similar degrees of cold, some display (*a*) no colour change, (*b*) a partial colour change, (*c*) complete colour change, (*d*) complete colour change repeated in subsequent winters, *even without renewed exposure to cold*.

(5) The degree of cold at the time of the autumn moult has a direct influence on the 'purity' or brightness of the white of the hair. When the change takes place without the direct influence of cold, but as a result of exposure to cold the previous winter, the white hair is, in comparison, of a yellowish tinge. It is nevertheless much whiter than the abdominal hairs which are normally also white during the summer.

(6) The autumn moult is always more rapid than the spring moult—the latter lasting for several weeks. It is almost irresistible to associate this with the relative suddenness of winter snow-fall and the more gradual disappearance of snow in the spring thaw.

(7) In the spring moult and in the gradual form of the autumn moult, certain well-defined areas of the body shed their hair before others. Thus, for example, the head and neck may show no sign whatever of moult of either the under-fur or guard hairs, when the rest of the body is already white. The moult commences on the underside of the belly.

(8) The moult is 'staggered' both with regard to the areas affected and the order in which the type of hair is shed. Thus the white under-fur grows in before certain of the brown guard hairs are shed. This adds to the dramatic effect of a sudden change, as the animal remains superficially brown when most of its hair is in reality white.

(9) Superimposed upon the phenomenon of the autumn moult is a limited blanching of some of the brown guard hairs before they are shed.

(10) Re-exposure to cold prior to and during the spring moult does not affect the colour of the summer coat, which grows in brown.

The frequent statements still appearing in the literature to the effect that the stoat has no autumn moult can probably be accounted for by the facts recorded in paragraph 7 and the rapidity and suddenness of the moult. The summer coat may be shed so precipitately that the hairs can be observed actually falling off as the animal moves about.

Klino-kinesis in Paramecium

Mr. Yapp's communication on this subject[1] is of considerable interest because it suggests that temperature may be a more suitable stimulus than *p*H for making a quantitative investigation of klino-kinesis in Paramecium. A quantitative study is required to discover how completely the klino-kinesis scheme describes behaviour in gradients.

His statement[1], referring to the term *klino-kinesis*, that ". . . there does not seem to be any justification for its use, instead of the simpler term avoiding reaction, for the ordinary behaviour" calls for a reply. The special value of the term *avoiding reaction* is that it is plainly and vividly descriptive of what one sees Paramecium doing when it encounters a boundary where the intensity of stimulation changes suddenly. But Ullyott concluded[2] that the typical avoiding reaction (in Dendrocœlum) is a special case of the generalized type of behaviour in a smooth gradient, where there are no sudden changes of stimulation. If the reactions in a smooth gradient are called avoiding reactions, then this term loses its vividly appropriate character. The term *klino-kinesis* was invented[3] for the generalized reaction and intended to cover the avoiding reaction too, as it seems to do for Paramecium[4,5]; this term is further of value as part of a relatively homogeneous classification of elementary reactions[3,6]. It is worth while noticing that sensory adaptation is an essential feature of successful aggregation in the eccritic part of a smooth gradient, when a random turning mechanism is used[2,6], while it is apparently not so important at a boundary.

Mr. Yapp's conclusion would be justified, therefore, only if smooth gradients were merely "unusual experimental conditions" and sharp boundaries were the natural conditions in which "ordinary behaviour" occurred. I should have thought that in the habitat of Paramecium and on the microscopic scale involved, smooth gradients would be the rule and sharp boundaries the exception.

I agree that there need be no teleological assumption in using the term *avoiding reaction*[6]; but I suppose Mr. Yapp would agree that it would be a pity to use the term unless one could be sure that no teleological implication would be read into it.

Rapid Determination of Water in Animals and Plants

DR. L. G. G. WARNE[1] is, of course, correct in maintaining that toluene with its boiling-point of 110·7° C. is preferable to xylol (b.p. about 135° C.) in the method recently described by me[2]. Unfortunately in the work which is going on at Plymouth one has to deal with large quantities of water and it is much easier to obtain xylol at the present time than it is to obtain toluene. I would like, however, to point out that the determination of water is only a comparatively small part of the work.

A method was devised in 1938[3] by which it is possible to weigh accurately such organisms as prawns, sponges, fishes or aquatic larvæ or embryos without removing them from the water, and this has opened up a vast field for research, for having weighed the fish or sponge one can then begin to carry out a quantitative analysis. Surely it will be recognized by all that this must have a great advantage over the older method of first, more or less, drying the organism or tissue and then carrying out the analysis.

Since 1938 the technique has been greatly improved and it is possible to weigh the organisms with much greater accuracy; but, of course, it is not possible to weigh a living sponge or shrimp with the same accuracy that one can weigh a crystal of quartz or calcite, and even if one could do so the figure would be meaningless, for the weight of a living organism must alter from minute to minute if not from second to second.

The displacement method of weighing has been fully described and discussed and I trust that a full account will shortly occur in the *Journal of the Marine Biological Association*.

The method of determining the water in organisms as recently described may be of great interest in another direction, for it is well known that drying an organism either *in vacuo* or in the oven even at a temperature at which most of the tissues would be charred or largely decomposed does not remove the ***bound water*** which is of such interest in biochemistry. It is quite conceivable, however, that even the bound water is removed by distilling the tissue under xylol or toluene.

Whether I was or was not the first to apply the Dean and Stark's tube for ascertaining the percentage of water in a sponge or prawn is a matter of no concern to me, and my sole reason for publishing a short account of the method was that I was urged to do so by Dr. Joseph Needham after he had seen a Soxhlet extraction apparatus used as a Dean and Stark's tube as described in my recent communication. It appears, therefore, that the method is not too well known in biochemistry.

Scientific Help for the Home Guard

MAY I through the columns of NATURE ask the technical help of readers for the Home Guard?

Although excellent equipment is now available to the Home Guard of an orthodox nature through the official channels, it still remains possible to supplement this by private ingenuity. I am inaugurating at this School a course in unorthodox weapons, gadgets and booby traps, and I would value information and suggestions from readers who have technical knowledge about how to make any of the following:

(*a*) Alarms to be attached to trip wires, etc.

(*b*) Detonators and electric circuits enabling mines, etc., to be exploded from some distance.

(*c*) Booby traps, electrically and otherwise controlled.

(*d*) Smoke bombs and methods of producing smoke screens.

(*e*) Home-made explosives.

(*f*) Home-made inflammable materials, such as the well-known phosphorus bombs.

(*g*) Home-made periscopes and other optical instruments.

(*h*) Simple signalling apparatus, buzzers, etc.

(*i*) Bird calls and other decoy noises.

In short, anything the physical or chemical properties of which can be usefully turned by the amateur to the successful harrying of the enemy. It is, of course, essential that these tools can be made by the amateur out of odd scraps of material likely to be found ready to hand. Certain of the things in the above list are for the moment prohibited, but this does not mean that it will not be worth while having at least the recipes by us in case the ban is lifted, either legally or by circumstance.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN CANADA

THE twenty-fourth report of the National Research Council of Canada, 1940–41, includes the report of the president together with the reports of the directors of the various divisions (National Research Council of Canada. N.R.C. No. 1002: Twenty-fourth Annual Report of the National Research Council of Canada, 1940–41. Pp. 28. Ottawa: National Research Council of Canada, 1941). The former well indicates the extent to which Canada's scientific resources are being mobilized in support of the war effort. In addition to its former role the Council is functioning as a research station for the three fighting services of the Department of National Defence and also for the Departments of Munitions and Supply, and the president's report refers to the way in which the National Research Council has been able to turn its peace-time programme almost overnight into one of service in war. For example, the Section on Metrology of the Division of Physics and Electrical Engineering has been expanded to provide the organization required for gauge-testing, and to date there has been no delay whatever in dealing with this aspect of production. Similarly, the Radio Section was immediately turned to the development of secret radio communication and has made important contributions in the development of prototypes. The Section on Optics has dealt with the problem of optical glass and the manufacture of fire-control instruments, with the result that a well-equipped factory is already operating in Canada for the manufacture of optical glass and a wide range of fire-control instruments. The Section on Radiology immediately turned its attention to industrial radiology and has organized laboratories and trained personnel for inspecting castings at the various industrial plants. The Section on Electrical Engineering has been engaged on the design and production of secret gear and equipment in connexion with naval protective devices, while the Section on Acoustics has been devoting its entire attention to acoustic problems for the navy and the Section on General Physics has done much valuable work on the design of instruments, ballistics, etc.

In the Division of Chemistry the laboratories devoted to textiles, leather and rubber have been engaged in testing war materials, developing substitutes and the preparation of specifications for war materials. Research on the manufacture of ethylene glycol by direct oxidation has been continued with special reference to the stability of the catalysts. All research on methods of defence against chemical attack excepting training phases is directed by a special committee of which a member of the National Research Council is chairman and technical officers of the Department of National Defence and of the laboratories are members. This Committee has organized and directed more than twenty research projects with the various university laboratories and in the Chemistry Division at Ottawa, as well as supervised the manufacture of all the gas masks in Canada. In the Mechanical Engineering Division the wind tunnels have been engaged on many miscellaneous projects in aerodynamics, and extensive co-operative investigations on lubricating oils and fuels have been undertaken. The model-testing basin is engaged in studies in connexion with boats and floats, and considerable fundamental work has been done by the Division in the use of moulding plastic plywood construction. The Division of Biology and Agriculture has been concerned with many problems in the storage and transport of food which have become of prime importance owing to the difficulty of transport across the Atlantic. Medical research work has been carried out in close co-operation with technical officers of the Royal Canadian Army Medical Corps, and leading medical research men of Canada are working vigorously on important phases of war medicine. The National Research Council was also largely responsible for the organization of Research Enterprises Ltd., a Government-owned company formed for manufacturing certain special secret equipment from prototypes developed by the National Research Council. The report also refers to the intimate liaison established with the British Government and with research workers in Great Britain, and to the work of the Division of Physics and Electrical Engineering in selecting Canadian university men for special war service in the British Navy.

NEW SPECTROGRAPHIC OBSERVATIONS OF PECULIAR STARS

NEW spectrographic observations of peculiar stars were discussed by O. Struve and P. Swings, of the McDonald and Yerkes Observatories, at the Autumn Meeting of the U.S. National Academy of Sciences held during October 13–15. The McDonald Observatory of the University of Texas (which is operated jointly by the University of Chicago and the University of Texas) is equipped with a powerful ultra-violet spectrograph. Two large crystal quartz prisms and lenses of quartz or of ultra-violet glass transmit stellar radiations to the limit imposed by the ozone bands in the atmosphere of the earth. During the past two and a half years this instrument has been used to record the spectra of a number of peculiar stars which had heretofore been investigated only in the ordinary photographic region of the spectrum. The ultra-violet region of the spectrum contains many important features: the limit of the Balmer series falls in the near ultra-violet where the lines crowd together and where photo-electric ionizations produce a marked discontinuity in the distribution of the continuous spectrum.

Among the results obtained are several remarkable cases of changes in the spectra. Perhaps the most spectacular case is that of γ-Cassiopeiæ, which a few years ago was a normal emission line *B* star, and which in 1940 had an almost pure absorption spectrum with very sharp lines, while at the present time the absorption lines are broad and very diffuse. We know that the emission lines come from a tenuous shell around the star. For some, as yet, obscure reason the shell began to change a few years ago. The authors suspect that it started closing in towards the star, producing an intermediate stage spectrum of sharp lines. Finally, early in 1940, the shell must have largely fallen into the reversing layer of the star.

The opposite series of events has taken place in several other stars (*Z* Andromeda, *AG* Pegasi), where a new shell recently formed has expanded and has, in the case of *Z* Andromedæ, progressed from the sharp-line absorption spectrum to an almost pure emission spectrum.

These examples show that the processes of evolution in astronomy are not always imperceptibly slow. The outermost layers of stellar atmospheres are extremely unstable formations which often undergo marked changes in a few weeks or even days. Apparently these formations are supported by a delicate balance of three forces: gravity downward, towards the centre of the star, radiation pressure from the brilliant continuous spectrum of the photosphere directed outward, and radiation pressure within the Lyman alpha line of hydrogen from the tenuous shell. This latter force is directed inward in the deeper regions of the atmospheric shell, and outward in the outermost regions. A small disturbance of the balance of these forces causes the entire structure to collapse, if gravity predominates, or to expand, if the outward components of radiation pressure predominate.

USE OF SNOWFLAKE REPLICAS FOR STUDYING WINTER STORMS

By VINCENT J. SCHAEFER

Research Laboratory, General Electric Company, N.Y.

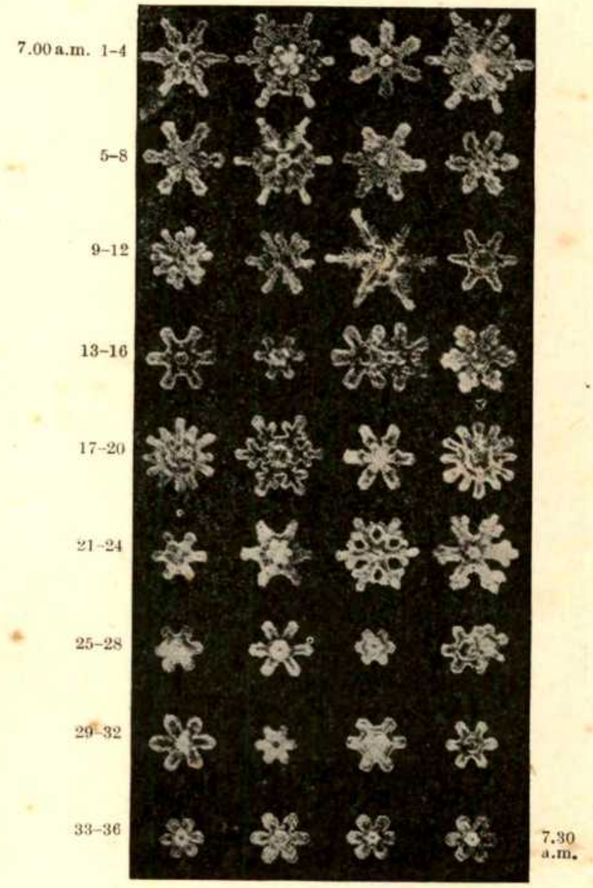
A METHOD was described last winter by me[1,2] for making permanent replicas of snowflakes, ice crystals and other forms of evanescent objects.

The technique, in brief, is to cover the frozen object with a cold dilute solution of an appropriate resin dissolved in a suitable solvent. After the solvent evaporates, a very thin continuous film reproduces in intimate detail all the surface configurations of the specimen. The substance of the original object is then removed by sublimation or by melting and evaporating, after which the resin shell, which optically appears identical to the original object, may be photographed and studied at leisure. A 1–2 per cent solution of polyvinyl formal[3] dissolved in ethylene dichloride (1–2-dichloroethane) reproduces excellent replicas of snowflakes and other forms of frozen moisture.

For collecting snowflakes a piece of black velvet stretched on a board is used to catch the specimens. A small drop of the resin solution is placed on a glass slide with a tapered rod. The rod, which still retains a small amount of the resin solution, is then immediately brought into light contact with the selected specimen and the flake readily adheres to it by surface tension. The specimen leaves the rod when it is brought into contact with the drop of liquid on the slide. All equipment is kept outdoors in a sheltered place throughout the winter.

Since the method of making permanent replicas is so simple, it would seem that those interested in winter weather phenomena might secure specimens from various types of storms for detailed study of these fascinating frozen forms in their possible relation to later meteorological occurrences. To illustrate these possibilities, the thirty-six photomicrographs reproduced herewith were obtained in a thirty-minute fall of large snow crystals at Schenectady, New York, U.S., during 7.00–7.30 a.m., March 12, 1941. During this short period, 150 specimens were collected and of these the 36 photomicrographs reproduced represent a typical cross-section of the replicas obtained. In securing these specimens the collecting board was cleaned every few minutes to make sure that representative crystals were secured throughout the fall. The photomicrographs were all made at the same magnification, so that the change in size as well as form can readily be seen in the photograph.

The climatic conditions when the specimens were collected showed a falling barometer at 29·70 in., a temperature of 26° F. with a north-west wind blowing. As happens frequently in this section of the United States, the crystal fall of large symmetrical crystals occurred at the close of a storm which deposited a total of about ten inches of snow. The snow of the storm contained a large amount of water (0·09 in. water per inch of snow) so that we would term it a 'wet' snow. At 7.30, when I stopped collecting, the symmetrical crystals were replaced by the more common non-crystalline forms of assymetrical flakes which continued for several hours, after which the wind changed and the skies cleared. It will be noted that the crystals collected at the start of the fall had a considerable amount of secondary deposits which gradually disappeared as they decreased in size and changed in form.



Other forms of frozen precipitation such as sleet, graupel and ice crystals, terrestrial forms such as columnar and tabular frost, as well as breath patterns and crystals of low melting point such as benzene and acetic acid may all be prepared in replica form by the method described.

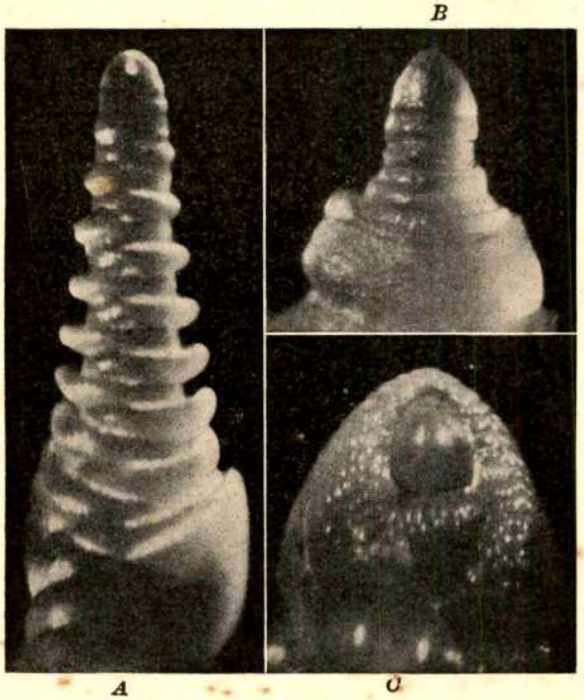
SHOOT APEX IN GRASSES AND CEREALS

By DR. B. C. SHARMAN

Botany Department, University of Leeds

THE lack of readily available illustrations and literature on the morphology of the shoot apex in the Gramineæ, coupled with the fascination to be obtained from actually viewing the living growing point and the newly initiated primordia in various stages of their early development, prompt a note for the benefit of other workers. Using a mounted needle under a fixed lens (or for preference, a dissecting-microscope) a little care will enable the outer leaves of most grass shoots to be removed one by one until the very young primordia and the growing point are revealed. Of the grasses so far studied, *Glyceria fluitans* R.Br. is by far the easiest to dissect, since its leaves are conduplicate and possess little sclerenchyma, etc., so that the tissues cut exceptionally well and yield to the needle in a manner curiously reminiscent of snow.



× 100 approx.

Figs. *A*, *B* and *C* show vegetative apices of *Lolium multiflorum* Lam., *Glyceria fluitans* R.Br. and *Triticum vulgare* Host obtained in this way: the photographs, however, do not adequately convey their delicate translucent appearance. In Figs. *A* and *B* the apices are viewed perpendicularly to the plane of the leaves, so that the young primordia are seen arising alternately on the right and left of the axis as small crescentic protuberances some little way back from the actual tip. In Fig. *A* two young leaves at the base of the apex have been removed because although they did not obscure the tip, they did hide the lower primordia. For a similar reason in Fig. *B* a single basal leaf was removed. In Fig. *C* the apex is viewed in the plane of the leaves, one primordium being seen overtopping the apex while a younger one is partly exposed to view: a still younger one was found on further dissection.

Although at the outset the initiation is comparatively localized, it soon spreads around the apex so that a more ring-like structure is produced giving rise to the encircling insertion so typical of grass leaves. The primordium grows fastest in the region of its origin, and thus after a while appears as a small cowl growing over the tip and enclosing the younger leaves (see Fig. *C*). In vegetative shoots the buds are formed in the axils of the leaves after they have reached this stage and are leaving the immediate proximity of the apex.

The lengths of the apices vary considerably, species in the same genus often having apices of very different dimensions, but those of individuals of any particular species are usually of about the same length, especially if shoots of equivalent stages are examined. It is difficult to find a natural measure to express the length of the apex when comparing one with another. A useful ready method of comparison is obtained by counting the number of successive primordia from the youngest until one is reached which is sufficiently well developed to enclose the youngest leaves and overtop the stem tip. When the apices of a number of species are compared, it is seen that they can conveniently be divided into the following three groups, although a number of intermediate forms can always be found:

(1) A long type where some 12–20 or more young primordia are maintained as in *Lolium multiflorum* (Fig. A). Bugnon[1] in a longitudinal section shows eighteen primordia on the apex of *Melica altissima* L. which might well come here. In this group there seems to be much variation, more vigorous shoots having considerably longer apices than weaker or less mature ones. There seems to be a continuous lengthening of the apex up to the onset of inflorescence production, when buds appear in the axils of primordia which do not yet overtop the apex and have not left the apical region. Bud development rapidly becomes more precocious and the early growth of the primordia slower until the buds are the conspicuous feature and the subtending leaves no longer excite notice.

(2) In the intermediate type, which is not sharply delimited from type (1) and perhaps ought to include it, there are about 5–10 primordia on the apex as shown in Fig. *B* for *Glyceria fluitans*. This is by far the commonest type and includes most of the herbage grasses (for example, it is found in Agropyron, Anthoxanthum, Arrhenatherum, Dactylis, Holcus, *Lolium perenne*, Phalaris, Phleum[2] and *Poa annua*). Although more vigorous shoots usually have longer apices, in general the limits for each species are more clearly defined in this group, especially in types tending to have rather shorter apices. There is some increase in the number of primordia borne as the shoot matures, but at the onset of inflorescence production considerable elongation occurs (cf. Evans and Grover[2], and Weber[3]) accompanied by an accelerated bud production exactly as in type (1).

(3) In the third type the apex is very short (Fig. *C*) and commonly bears only one or two leaf primordia. Avena[4,5], Coix, Hordeum[5], Oryza, Secale[6], *Sorghum sudanense* Staph., Triticum and Zea as well as *Phyllostachys nigra* Munro[7] and Saccharum have apices of this type. It is prevalent in the cereals but is not limited to them. Typically, the apices remain short during the vegetative period and only elongate rapidly and suddenly at inflorescence production

when the axillary buds arise precociously, giving the appearance of double protuberances formed from the buds and the subtending primordia which remain as crescentic ridges (Purvis[8] and Bonnett[5]). This sudden elongation is very marked in Zea: in Triticum, on the other hand, there is a slight tendency to apex elongation during the initiation of the last three or four vegetative leaves.

It has been suggested[9] that apices of the short type are characteristic of annuals and that perennials tend to have the longer types, but the occurrence of short apices in Phyllostachys and Saccharum, and of long apices in *Poa annua* and *Lolium multiflorum* are not in accordance with this. Nor can the type of apex be correlated with a monocarpic or polycarpic habit since although many (? most) bamboos of the genus Phyllostachys, (see Kawamura[10]) die after flowering, this is not likely to be the case in Saccharum when it does happen to flower. Again, although *Lolium multiflorum* is a type with a long apex, after it has flowered a clone can often only be maintained with difficulty.

Nor does there appear to be any connexion between the degree of tillering and the type of apex. Coix, Phyllostachys, Saccharum and winter wheat all tiller well but have short apices. In a number of strains of maize with a more pronounced tillering characteristic, kindly sent by the Maize Genetics Coöperation of Cornell University, the apices were indistinguishable from normal non-tillering types.

The clue to the length of the apex probably lies in the behaviour of the provascular strands. If these are initiated early in the primordium and rapidly link up with the system lower in the stem, then early in its development the young leaf and its portion of the apex will be able to tap food supplies coming back from older leaves, and thus be able to grow rapidly so that it soon encloses the younger leaves and overtops the stem tip and at the same time is removed from the extreme growing region. In cases where the development or the linking up of the provascular strands is slow, there will be a 'piling up' of primordia and the consequent production of the long type of apex.

INFLUENCE OF TEMPERATURE AND *p*H ON THE C/N RATIO OF SOILS

By PROF. N. R. DHAR and N. N. PANT,
Indian Institute of Soil Science, Allahabad

WITH ordinary soils the results obtained in different countries show that as a rule the higher the mean temperature of the soil the greater s the carbohydrate/nitrogen (C/N) ratio. Dhar and Mukherji[1] have reported that in India the C/N is highest in the soils from the Punjab with the average value of 14·4, in the United Provinces it is 11·3, in Bihar it is 9·2 and in Bengal the ratio is 9·1. In Wales it is 9·2. In the State of Washington after long cultivation the value is 10·2. In the Sudan it is 12·6 and in the Transvaal it is 14·4. It seems, therefore, that the C/N ratio of normal surface soils is in general an indication of the average temperature of a locality.

Experiments carried on by Dhar and Mukherji, in which normal garden soil samples collected from Allahabad, with a C/N ratio of 10·1, were kept in an air oven at 80° for more than two years, showed an increase in C/N with time from 10·1 to 13·5.

These results of Dhar and Mukerji showing that the C/N ratio increased in normal soils with increase of soil temperature are in agreement with those obtained by McLean[2] but are contrary to those calculated by Jenny[3].

In alkaline soils collected from Soraon and Saidabad near Allahabad and from other places like Bangalore (Mysore) it is observed that the C/N ratio of such alkaline soils is small and varies from 4·0 to 7·5.

(*A*) Soraon and Saidabad (Allahabad) Soils (0–9 in. depth)

*p*H	C/N
10·4	4·0
10·5	4·9
8·4	6·1
9·3	6·8

(*B*) Bangalore Soils (0–9 in. depth)

*p*H	C/N
9·8	6·7
8·0	6·7

When these alkaline soils are treated with reclaiming agents like molasses and press-mud or oil cakes the C/N ratio tends to increase as in normal soils. These results seem to be highly interesting, and show that alkalinity favours carbohydrate and cellulose oxidation more than protein metabolism. Alkalinity thus seems to oppose the influence of temperature on the C/N ratio of soils. Moreover, this small ratio of C/N in alkaline soils makes it clear that ammonium compounds do not occur in large quantities in such soils and the nitrogen store in soils may be the more complex protein compounds which do not undergo oxidation in the alkali soil as readily as carbohydrates and celluloses.

On the other hand, in soils where there is a tendency for the generation of acids, as in most cold countries, the C/N ratio should have a tendency to increase. In other words, in soils where the *p*H range is smaller than 7, it is expected that the protein oxidation would be favoured more than the oxidation of cellulose and carbohydrates. This conclusion is fairly well supported by the following observations on C/N ratio of acid soils in different countries.

The *p*H of soils collected from different countries are as follows:

Scotland	5–6·4
Finland	5–6·4
Japan	4·5–6·9
Denmark	6–6·9
Sweden	6–7·4
Java	6·5–7·9
Egypt	7–9
North India	7–10·8

It may be seen from the above data that, in general, the soils of cold countries have a tendency to acquire a lower *p*H value than those of warmer countries. The *p*H of some of the soils collected from different cold countries is given in the table below against the C/N ratio of such soils.

In Siberia some soils show a C/N ratio of 13·6.

It seems that two opposing factors are at work in controlling the C/N ratio of soils. In tropical countries,

	pH	C/N	Depth	Place	Investigators
Red Loams I	6·4	18·30	0–6 in.	Chaubatia (Kumaun Hills), India	Mukherji and Das
	6·8	14·20	0–6 in.		
Brown Forest Soils II	6·2	18·20	0–8 in.		
	6·3	12·70	0–1 ft.		
	6·5	18·90	0–5 in.		
	6·8	16·10	0–5 in.		
	6·2	19·04	0–1 ft.		
Podsol III	6·8	16·60	0–7 in.		
	6·0	16·90	0–1 ft.		
Wiesenboden IV	6·4	16·0	0–6 in.		
	6·7	15·84	0–9 in.		
Podsol V	3·70	29·24	6–9 in.	Shropshire, England	Davies and Owen[5]
	3·13	13·36	9–19 in.		
	3·73	23·48	19–23 in.		
Podsol VI	3·0	129·0		Northern New Guinea	Hardon[6]
	4·3	51·69			
Brown Earth VII	5·26	24·60	0–10 cm.	England	Muir[7]
	5·35	19·40	20–30 cm.		
Brown Plains Solod	6·17	23·96	0–3 in.	Saskatchewan, N. America	
	6·20	29·00	3½–7½ in.		
	7·07	21·90	7½–9 in.		

due to the influence of light and high temperature, the organic matter, which acts as a buffer, is readily oxidized from the soils, which have thus the tendency to be alkaline. With such soils, before the alkalinity is reached, the C/N ratio has a tendency to increase as observed by ourselves as well as McLean. But as alkalinity develops, the cellulose and the carbohydrates are oxidized more readily than the protein of the soil and the C/N ratio falls off. Hence the temperature effect is nullified by the alkalinity influence.

On the other hand, in soils in temperate and subtropical countries the organic matter added to the soil or present therein is not oxidized readily and hence such soils have a tendency to be on the acidic side, as illustrated above. But before it becomes acidic the C/N ratio may be in the neighbourhood of 10·0, as is frequently observed. But when the soil becomes acidic, the C/N ratio tends to increase. This is because in protein metabolism, ammonia is usually the first product of such oxidations and hence acidity may help the removal of one of the products of protein oxidation, namely, ammonia, and thus may help protein metabolism. Hence, in acid soils, protein metabolism may be faster than the oxidation of cellulose or carbohydrates, resulting in the increase of C/N ratio of such soils. This is why Jenny has obtained high C/N ratios in soils from cold countries.

The above conclusions are supported by the observations of Jensen[8] showing that 20–25 parts of carbon are oxidized in the nitrification of one part of nitrogen nitrified in acid soils, and by the facts that the acid soils in the paddy fields of Siam have 11·4 as the C/N ratio and the C/N ratio of virgin or prairie soils falls off from 13·6 to 10·5 after cultivation as observed in the United States and that the C/N ratio of Mauritius soils increases with increasing rainfall and soil acidity as recorded by Craig and Halais[9].

SCIENCE AND SOCIETY

MUCH indeed has happened since Prof. J. R. Marrack in 1937 contributed his stimulating essay on the "Social Implications of Biochemistry" to the volume of essays "Perspectives in Biochemistry" which was presented to Sir Frederick Gowland Hopkins by past and present members of his laboratory on his seventy-fifth birthday. It is now widely realized that not only, as Prof. Marrack pointed out, does the future trend of biochemical investigation into problems of nutrition depend largely on what form society takes, but also the whole trend of scientific work or even thought. The impact of society on science is as unmistakable as that of science on society.

That recognition has already found expression in important developments both in the field of science itself and in the world of politics. We have seen the formation of a new Division of the British Association for the study of the social and international relations of science. Nuffield College, Oxford, has been established as well as the National Institute of Economic and Social Research. Although the stress laid on research in the Report of the Royal Commission on the Distribution of the Industrial Population has yet to be implemented, the proposal in the minority report for the establishment of a commission of research covering all matters—land, agriculture, minerals, amenities, etc.—affected by national development finds widespread support.

In the field of politics account has been increasingly taken of the new knowledge of nutrition in handling questions of food supply and food production during the War, and there is evidence that Government is prepared to face the questions involved in the provision of diet standards based on the biochemical work of the last thirty years, and at least implement the possibilities thus opened up of raising the standards of health of a large proportion of the people of Great Britain through the provision of an economic and better diet by expanding social services, and a determined attack on malnutrition and its causes. That much, at least, is implied in the conception of a social minimum now gaining support, and its application is by no means limited to the people of Great Britain. Its bearing on the questions of Colonial welfare and development and on the feeding of the people of the enemy-occupied territories after the War, as well as on European economic and social reconstruction, are equally to the fore. The formation of the Bureau under Sir Frederick Leith-Ross announced at the second meeting of the Inter-Allied Council in September is evidence that practical effect is being given to such ideas, and the American co-operation then indicated will assuredly not be withdrawn or diminished now that the United States has entered the War.

The most striking feature of all such developments is, however, the immense amount of *ad hoc* inquiry, investigation and research which is still required over the whole range of the social sciences as a basis for policy and action. It is this that raises such studies to the priority level even in war-time, if having won the War we are not once again to lose the Peace. Even in the field of internal reconstruction the same condition holds. Lord Reith has already indicated the importance he attaches to research in a statement on the work of his Department made as long ago as February last year, and Mr. Greenwood, the Minister in charge of reconstruction, has stressed the importance of such surveys as those of the whole field of social insurance and allied services including unemployment assistance and workmen's compensation which Sir William Beveridge has undertaken. Further, plans are being made for the Agricultural Economics Research Institute to conduct a survey of problems of agricultural reconstruction when the necessary funds are assured. Mr. Greenwood has referred particularly to the North-East Regional Reconstruction Group of which Prof. J. H. Jones is honorary secretary. This is only one of several regional reconstruction organizations. Also, there are the investigations of Political and Economic Planning, and particular importance is attached to the work of the Demographic Survey of the 1940 Council. Mass observation, too, makes valuable social surveys, though we believe its scope and the intensity of its work are rather limited compared with similar social surveys and observations frequently made in the United States.

It is clear, therefore, that the importance of social research is recognized by the Government and that the co-operation of other institutions and bodies, whether local or regional, industrial or professional, is welcomed as leading to the development of new technique. Despite these numerous activities it also appears that not only is some real co-ordination and central guidance desirable but also much more effective financial support. In the absence of greatly extended Government assistance there is no evidence that many of these activities will be able to make more effective contributions than the Social Science Department or Economics Research Section of those Universities like Manchester and Liverpool which have already entered the field of social economics.

It is no disparagement of the work which has been carried out by such departments or by the National Institute of Economic and Social Research to suggest that with extended financial resources they might already have made much more important contributions to the solution of social problems of national and not merely local importance. This question of finance, with the further question of objective research, is in fact the vital one to consider in judging the proposal recently advanced by Prof. George Catlin in a letter in *The Times* of December 22, although regard should be had to the general background already outlined. The urgency of the need for more intensified research in the social sciences and a scientific examination of the impact of science upon society has been repeatedly stressed in NATURE over the last decade or so. A more biological approach is also an urgent need in the study of local, national and international policies, as is well argued by Mrs. Neville-Rolfe on p. 90—a thesis which she and others have been urging for some time past.

Prof. Catlin expresses his regret that the opportunity was lost ten years ago of establishing a social science research council as a genuine academic council representative of all branches of the social sciences in Great Britain. Such a scheme involving the survey of projects for research, the allocation of financial assistance and aid in personnel for the prosecution of such research and the direction of endowments into fields the probable fertility of which had been explored, would have done more than augment the resources of the struggling university departments or other research organizations. It would have provided an organ for an authoritative voice of the social sciences and immensely strengthened their position in respect of objective research.

On p. 88 Prof. Catlin urges strongly that the establishment of a representative social science body, of the highest academic standing and the fullest professional knowledge, that can freely express itself in a fashion that will command attention within this sphere is required to avoid the natural limitations of the Royal Society and the British Association with regard to social science. Such a body could have corrected many false conclusions in the past and could assist the Government and public authorities in many directions likely to be of paramount importance. Moreover, long-range work under such a council in fields, for example, like economic reconstruction and population studies, would be beyond suspicion of political bias.

This latter point is probably of the more importance since there is a sense in which the scientific work and thought which are required to provide the material which will enable social structures to be designed with full knowledge by Governments and administrators inevitably involves entering the political field. This, as Sir Richard Gregory has pointed out, is another matter from political partisanship, and provided the functions of the expert and the administrator are not confused there is no justification for the fear of science becoming entangled in contraversial politics presenting a bogy to the advance of the social sciences by the application of impartial scientific methods and principles to the problems involved in them. Indeed, Prof. A. V. Hill, in supporting Dr. Catlin's proposal, has suggested that the Royal Society might help, as it helped in establishing the British Academy in 1902, and while urging the application of the results of science to human betterment has uttered a warning against allowing our desire for betterment to upset our scientific conclusions or bias our scientific judgments.

Prof. Catlin's proposal has also been warmly welcomed in the correspondence columns of *The Times* by Mr. F. S. Stone, acting secretary of the National Institute of Economic and Social Research, who, indicating the willingness of the Institute to cooperate, points out that the Council of the Institute does not attempt or claim to cover many important branches of the social sciences such as anthropology and social psychology, although as Mr. Charles Madge has pointed out, the Council of the Institute is potentially the social research council for which Prof. Catlin asks. We take the view, however, that research in the social sciences to be effective must cover a much wider field—in fact, it must invoke the aid of almost every branch of science. We cannot, therefore, subscribe to Mr. A. Farquharson's view, expressed on p. 101, that "the narrower field [of sociology] may be appropriate as defining a useful field of operations for the present and that the wider view should not be dropped altogether out of sight". We envisage a much wider basis for the proposed activities, and this is illustrated by the other articles published in this issue. The foundation should be as broad and comprehensive as possible if the proposed organization is not to make the grave error of following a too narrow and specialized path. The President and Honorary Secretary of the Royal Anthropological Institute have also supported the proposal and indicated the willingness of that Institute to cooperate. Moreover, in their letter they stress the urgency of the need for such action.

The need for some kind of central research organization with adequate resources at the present time appears to be generally accepted, though the exact manner in which this need should be met gives rise to some difference of opinion. Prof. Abercrombie, stressing the need for scientific research into population problems, family units, industrial location, quality of farmland, transport, etc., with reference to planning for reconstruction, has suggested reconsideration of the proposal in the Minority Report of the Barlow Commission for a permanent commission of research as another alternative to the social research council worth examining.

The articles published in this issue of NATURE indicating the need for research in the various branches of sociology leave no room for doubt as to the imperative necessity of some such step. A much more generous endowment of such research through Government grants and the great foundations and trusts is to be hoped for to redress the disparity between our research effort in the biological and social sciences and in the physical sciences and to check the dangerous gaps arising through the unevenness of the whole research front.

The present proposals very clearly cannot be considered altogether without regard to the present structure and organization of scientific research as a whole in Great Britain. Moreover, there is some difference of opinion among our contributors as to the exact form of the organization required, and some clarification of thought as to the functions which it should serve must precede the establishment of any new body. Sir Frederic Kenyon, for example, visualizes some organization on the lines of the Royal Institute of International Affairs or of the Institute of Chemistry, for the collection of facts and the formation of opinion or formulation of principles in social science. Mrs. S. Neville-Rolfe suggests rather the formation of an Institute able to act in a consultative-directive capacity. On the desirability of a central research institution competent to attract investigators of distinction, to encourage co-ordination and concerted planning there is general agreement. Adequately financed and staffed and ably directed, such a central research organization, through its various departments briefly envisaged in the following articles, could make an immense contribution to the wise and effective use of our resources both in war and in peace.

There seems to us a grave risk involved in the suggestion that a Social Sciences Research Council be established along lines similar to those of the Agricultural and the Medical Research Councils. The ramifications of the social sciences go much farther and involve a larger number of special sciences than either of the other two, which are naturally confined to more or less well-defined though limited fields of action. Furthermore, these two already existing Councils have great assets in research personnel and accommodation for medical and agricultural research already existing in the universities, colleges and institutes throughout Great Britain. This cannot be said for the social sciences. Most of the special sciences become involved in sociology. Some receive attention from the point of view of their impact on society; but this only in certain universities and the various institutes already existing for the purpose which are specialized or are very narrow in their terms of reference. In the case of the social sciences, therefore, it seems that what is most desirable is the formation of a central institute with a permanent staff where research could be carried out or organized and deputed to university or other centres which already have the necessary staff and material. Research should be the key-note of the organization of such an institute; data would be gathered, sifted and correlated; funds administered; information supplied; and courses of lectures, refresher courses and vacation schools organized.

Platforms for the expression of points of view, for symposia on the social sciences and for discussions concerning the impact of science on society already exist and have done and are doing useful work. Almost every section of the British Association, for example, discusses in some way or another the social implications of its own particular scientific discipline, and the Division for the Social and International Relations of Science, under the chairmanship of Sir Richard Gregory, has already done work of inestimable value along these lines. Then there are the other more limited institutions and societies. But all these exist chiefly for the expression of points of view and for the determination of policy. Only within very narrow limits can they be expected actively to carry out research, and it is research in the social sciences which is so urgently needed. For this, some new form of central organization is, without doubt, badly needed, and now is the time for its foundation. Problems peculiar to war-time would receive prior claim, and thus would be laid a sure foundation for the development of the organization after the War, so that science could play a more practical part in the establishment and keeping of that kind of peace for which everyone is hoping.

CENTRALIZED RESEARCH IN THE SOCIAL SCIENCES

THE CASE FOR RESEARCH IN THE SOCIAL SCIENCES

By Prof. GEORGE E. G. CATLIN

Sometime Professor of Politics in Cornell University

IT is common ground that the task of social reconstruction after the War is going to take a prerogative position. Upon its success or failure is going to depend the future condition of Europe, and not only of Europe. In the alternative, we shall have not only a revolutionary epoch; but also a revolutionary epoch that is not even successful. The question here is whether this reconstruction is simply going to be carried through by practical men, dominated by the departmental notions of their own personal and limited experience, or whether the politicians are going to call in those who have, as a professional matter, made a systematic survey of the entire relevant data.

There is a second issue which, at the risk of paradox, I would venture to call even more important. It is that of the advancement of science. The social sciences have been embarrassed by the highly emotional and personal nature of much of the subject-matter with which they have had to deal—although it has been pointed out to me that medical science might have been overwhelmed by the same embarrassment (which has periodically threatened it) if it had lowered its standards of objectivity. To say that every economist is liable to be prejudiced, as the late J. A. Hobson said, is clearly true. To say that therefore there can be no economic science does not follow. The social sciences have suffered from the prejudice of those whose interests were liable to be undermined—so did the physical sciences in their day, but the enemy was then dubbed 'superstition', not 'practical sense'. They have suffered, as Hobbes said, from politicians who regarded them as 'dangerous', and even from eminent universities which have regarded them—as also the physical sciences were once regarded—as undignified upstarts. The great University of Cambridge declined to accept a grant for a chair of sociology, while the ancient University of Oxford had many, doubtless entirely necessary, chairs of divinity in various forms.

While the social sciences have been regarded as wicked attacks on the humanities by the humanists, they have, alas! been regarded as bastard little brothers by the physical and natural scientists. For some purist academics scarcely anything at all has been science save mathematics and mechanics. For others, no less dangerous, everything capable of being the subject of lengthy meditations has been *Wissenschaft* and science. As a kind of compromise, when the overwhelming practical importance of these sciences in a disturbed world could no longer be denied, the awakened practical men and journalists asked for 'scientific opinions', and the awakened citizen-scientists began to express their opinions in profusion. Astronomers, biologists and physicists talked about the nature of the State and the rectitude of credit and tariff, as did also the astrologers, and every writer of fiction or *belles lettres* who had what is called 'a name' and whose articles would sell easily in the commercial, popular press. On the whole, speaking from the point of view (which, of course, has to be considered) of the pay-box, the astrologers led.

For myself, I happen to be a humble political scientist who has spent twenty-two years on the job. The science is immature. Few even of my own colleagues agree with me in everything—but then, neither do the mathematicians agree. That there is a political science I contend along with Machiavelli and Hobbes, Spinoza and Bentham, Mill, Sidgwick, Marx and Lenin. Unlike the last, I hold that it can most helpfully at the moment be provisionally interpreted by the Hobbes-Adler hypothesis of the quest for power and that many of its hypotheses are capable of empirical and quantitative demonstration. These are deep matters, suitable for discussion elsewhere. But, since I put this argument forward (and I admit that it was received with acute scepticism) the work of Bertrand Russell on power, and the revolutionary 'mass observation' studies of Harrison and Madge seem to have done something to confirm it as the tenable hypothesis which alone I submitted it to be.

Political science, however, is perhaps the weakest and most uncertain (although, if Plato be right, the most august and promising) of the social sciences. Whatever be the quarrels of the schools, who will deny that a trained economist is more qualified to discuss economics than a layman ? Or a statistician statistics ? Or a psychologist psychology ?—although I have heard learned humanists at college high-tables demonstrating with finger and port glass that experimental psychology was *contradictio in adjecto* and, moreover, a waste of college funds.

The Social Science Research Council of America, for which I once had the honour of acting as a director of research on the subject of the socio-medical controls under the Eighteenth Amendment, has in its wisdom decided to include, within the field of the social sciences, economics, political science, sociology, anthropology, statistics (including vital statistics), psychology and history. The case of history must seem dubious, since it is generally agreed that there can be no science of history as such, but as a fact-classifying discipline the practical advantages of the inclusion of Clio in this company may perhaps outweigh the disadvantages. Plato's rule about the preliminary study of mathematics and Lord Kelvin's rule about the measurable nature of the material of exact knowledge are remembered. As has been well recognized in the School of Human Relations (which owes its establishment in large part to President Hutchins (now of Chicago)), there are various claimants for admission to the circle such as social hygiene on the margins of medicine, and criminology on the outskirts of law. However, the present system works.

This Social Science Research Council began in the United States in the middle of the 'twenties in quite a humble way, with a modest budget. It boasted no offices and not even a salaried secretary, but only a 'secretary to the chairman'. At this time Professors Charles Merriam and Wesley Mitchell played leading parts in getting the organization firmly established. There was little sign of that 'American over-organization' of which my old friend, Professor Graham Wallas, was afraid. Later, first Professor Lynd and then Professor Crane were appointed as secretaries general. The two famous reports on Economic Trends and

Social Trends were carried through by the Bureau of Economic Research and the Social Science Research Council respectively, the second under President Hoover's patronage and bearing his name as "The Hoover Report". The great prestige of the Council, with its princely offices, is something that has been built up on solid and vital work.

The failure of the Eighteenth Amendment, at great public cost and with inestimable damage to law observance, showed the danger of social legislation and even of 'noble experiments' carried through without adequate psychological understanding or sociological analysis. Nevertheless, it was clear, in about 1929, that there was going to be more social legislation deeply affecting the way of living of the community. The question was whether it was to depend upon power or upon knowledge, or upon mere muddle and afterthought. Financial aid was obtained from the Halley Stewart Trust in order to establish a preliminary committee to survey the social research work being carried out in Great Britain, as has been mentioned by me in the columns of *The Times*. Sir William Beveridge, Profs. Carr-Saunders, McGregory, Pigou and Wallas, Lord Stamp, Messrs. Farquharson (rapporteur), Stanley Unwin and others served. Some of us felt that the final report might profitably urge the establishment of a Social Science Research Council of Britain, and this was in some measure done. However, for reasons hat need not be discussed here, the broader scheme proved abortive. Largely owing to Lord Stamp's activity, the Institute of Economic and Social Research was established, to do valuable work. After talks with Lords Astor and Tweedsmuir and Mr. Tom Jones, the other scheme died. The humanists were not very sympathetic and there was some confusion between the fields of social research and social service, and also doubt whether only economics was mature enough to be regarded as a science.

At the same time suggestions were put forward for a scheme for strengthening legislation by party political research (a matter of interest to Lord Astor and to Mr. Wedgwood Benn, Mr. Roden Buxton, Sir Oswald Mosley and the Fabians) and for a Social Advisory Council to the Government, the latter being put forward in memorandum form in 1930 to Mr. Ramsay MacDonald. Later, the Economic Advisory Council (a very unfortunately constituted body) was established. The design, however, of those who were interested in thus 'rationalizing politics' was not to confound party politics or governmental policy with academic and long-distance research, but precisely, by he establishment of different although related organs, o distinguish these fields of propaganda, policy and research which are so habitually confounded.

For this reason, although I have noted with interest Prof. Patrick Abercrombie's suggestion in *The Times*, nd I believe there is a very strong case for reconstituting the ineffective Economic Advisory Council, would emphatically not be in favour of establishing ny academic council under the Cabinet, and still ess (Heaven forfend !) make any Civil Service department. Absolute independence, the staking of personal academic reputations for integrity, the highest tandards of objectivity, long-distance research—hese are the requisites. It by no means at all ollows that such research has no practical conseuences, and this of the most vital character.

I would take research into population changes as one instance. Great prejudices, economic and religious, are stirred. The sovereign pride and the national and racial rivalry of States are affected. It is all very difficult—and all very practical. The final war is the biological war. Many of the facts are matters of 'cold' statistics, although, of course, ultimate questions of values do not come within the purview of science. The medical man, for example, works on the hypothesis that the life of the patient should be preserved. There may be occasions when morally it should not. It is outside his province to decide the morals of infanticide but only to carry out the Hippocratic oath. That is his hypothesis.

There is probably a strong case for establishing an Institute of Vital Statistics, Demography and Social Biology. But no departmental institute can fulfil the work of the Council, nor can the institutes representative of other departments—anthropology, sociology, experimental psychology, industrial psychology or the various societies such as the Royal Historical Society be expected to serve under its banner. A general council is required.

On the analogy of what has already been done or recommended, I would suggest that the functions of a Social Science Research Council should be (*a*) to survey the field of the social sciences and to prevent overlapping in research ; (*b*) to provide a channel of financial aid from individual benefactors, public foundations and the Government ; (*c*) to pass upon and initiate schemes for research ; (*d*) to provide finance and aid in the provision of personnel and office facilities for such research ; (*e*) to publish, where desirable, the results ; (*f*) generally to promote the interests of, and to advance, the social sciences ; (*g*) to be an organ for voicing the collective opinion of social scientists on such occasions as it may be desirable to express them ; (*h*) to represent the social scientists of Great Britain at relevant international gatherings ; (*i*) to aid the Government and appropriate public bodies in social scientific research, when called upon to do so. I do not contemplate the Council members themselves being called upon, as such, to undertake research. This should be done by individual experts who are recognized authorities in their special subject, a background of advisers being supplied by sub-committees *ad hoc*. The function of the Council should be initiatory and generally supervisory.

The constitution of the Council involves more difficulties in Britain than in the United States, where every discipline has its own national association. I would, however, suggest that every holder of a chair or a readership in the selected subjects in the British universities should be *ex officio* a member, and probably also the directors of the relevant institutes and the presidents of the recognized national societies. It will be borne in mind that their main executive function, apart from the raising of funds, which can be left to the officers, would be the appointment of vigorous sub-committees to do the actual work. A special relationship would need to be established with the Royal Society, the British Academy and the British Association. But the less the American model, in constitution, is departed from the better—although, of course, a British institution can be expected to operate in a typically British rather than a typically American way.

The establishment of such a body, such as would gratify a Petty or others of the founders of the Royal Society, might well be one of the greatest steps for the advancement of science and one of the most original contributions to far-sighted and reasonable government in our century. It could do something to vindicate democracy as government by discussion, comment and reason, against government that claims to be efficient but rests on the principle of mere party power. Before there can be what is readily called 'scientific government' (be it 'scientific socialism', 'scientific business', or what have you) there must first be science, not apologetic but organized, independent, authoritative.

BIOLOGY AS A SOCIAL SCIENCE

By MRS. S. NEVILLE-ROLFE, O.B.E.

IF a social structure that provides for the emotional freedom and development of personality is to be the outcome of the present struggle, then an immediate effort must be made to harness individual emotional energies to this purpose. If the present world-wide destruction of man and his material assets by his fellow-men is not to inflict irreparable damage on civilization, man must make a supreme effort to safeguard and improve human quality. He must collate his scientific and spiritual values —to this end the gulf between the scientific and extra-scientific leaders must be spanned by as wide a bridge of common agreement as possible—direct his knowledge and energy to the fostering of individual emotional maturity and to the conscious control of his own evolutionary processes. Both intellect and emotions must be mobilized in the pursuit of a satisfying purpose in life, by applying to man the existing knowledge of social biology and by directing the desires and capacities of the present generation to further research (related to man) on personal and genetic development.

The knowledge and experience drawn from all parts of the world and from all groups working on biological problems—both theoretical and practical —should be immediately collated by an organization designed to promote its application and to foster further research.

To this end it is suggested that an institute having social biology within its purview should be called into existence, representative of scientific thought and world-wide experience, and able to act in a consultative-directive capacity.

Social biology is interpreted, for the purpose of this article, as including all those branches of science and administration directly concerned with man in relation to the genetic, traditional and environmental factors that shape his personality and influence his social relationships.

Many branches of general biology have contributions to make, including functional anthropology, genetics, psychology, physiology and biochemistry. The educationist, sociologist and statistician are also needed as channels of application as well as the administrator, the statesman, the medical man and the judiciary.

The time-lag between knowledge and practice in its application to the quality of man himself is unduly long. If the causes are recognized, it may hasten their removal.

Social Effects of Unrecognized Biological Factors

It has in recent years become obvious to some of our Empire administrators that man is being shaped to a large extent by his environment. The effect of soil erosion on tribal customs ; the effect on nutrition, and ultimately on fertility, of relating currency to cattle ; the effect of soil starvation and ove recruiting of labour on tribal and family life ; th break-up of tribal life brought about by intellectual imposed changes in spiritual values—all are problem of social biology and are now seen by some with clarity for what they are.

We recognize the effect of imposing Western factu knowledge on peoples whose emotional values ar still governed by tribal tradition. We can see th results of this unconscious but large-scale experimen in social biology among the detribalized African living in ports and industrial towns. Their emotion lives rooted in the traditions and governed by th values of the tribe, its family structure, its lan tenure, its totems and its magic are not integrate with the newly acquired factual knowledge, or wit the required behaviour pattern of a more comple culture. Unless these former deep-rooted an emotionally desired standards and customs are carefully re-interpreted and related to the higher value embodied in the European culture it is sought t impose, so that these are willingly accepted, there is deterioration in character, personal unhappines and a sense of frustration. Some apparently successfu experiments in social biology have already bee made—for example, the substitution of competitiv prowess in the hunt or in sport for the head-huntin qualification for full tribal membership and marriage and the modification of the original mutilatin initiation ceremonies to a form adapted to the ritu entry to a Christian community.

While we recognize the emotional childhood of th African and rightly explain his irresponsibility as du to the personal conflict between his own values an new knowledge, we have not recognized the sam conditions as obtaining in ourselves.

Psychology, anthropology and endocrinology hav of recent years widely extended our understandin of the emotional nature of man. Many well-known phenomena hitherto quoted as evidence of th 'unchangeability of human nature' are now seen a the result of infantile desires being unrecognized a such by the intellect and remaining as overshadowin influences or subconscious prejudices often impellin the adult to behaviour entirely at variance with th dictates of reason. A factor of supreme importance but not yet consciously applied, is that the firs appreciation of 'values' comes through the emotions An intellectual giant may be gravely frustrated i personal life by an uncontrolled temper, arising fro subconscious emotional causes, or by an emotiona immaturity which denies him the harmony of adjustment in marriage.

Human energy has been directed to training th intellect but has ignored the emotions. Knowledg will not affect behaviour or lead to action unti implemented by emotional driving force, which ca only be secured when both mind and emotion accep a common objective and purpose in life. Though this is known to the psychologist, it is not adequatel applied by the educationist, nor is it generally understood by the public.

Emotional Development of the Child

The Child Guidance, the 'Home and School' an the Mental Welfare Councils, and a number o individuals are working out techniques for th emotional development of the child, on the basis o existing knowledge, and indicating lines of researc and inquiry.

No systematic popular education has, however, yet brought to parents or to administrators that understanding of the emotional make-up of the young child that is vital if its needs are to be met. Under war conditions the quickest and most effective way must be sought to give the children of to-day the best opportunities of developing into emotionally balanced and mature adults capable of being responsible citizens of a real democracy.

To-day, even when an administrative reform is made, the general ignorance of psychology and social biology results in the cause of the reform not being understood by those who carry it into effect, thereby nullifying the intended advantages.

A number of the progressive local authorities and philanthropic organizations have already abolished the large institution for the care of children; but many have not appreciated that the reason for the change is to provide for the satisfaction of the child's emotional need for parent-substitutes, and therefore they omit to provide sufficient staff in the cottage home to enable any one person to express affection to the individual child, or to enable the child to have the emotional outlet essential to its development. They ignore the psychological reason for the change of policy. Nor is it appreciated that substitutes for *both* parents are required. A widow, untrained, charged with the entire care of twelve children, single-handed, has no time for 'mothering'; the frequent employment of widows, though it reduces the cost to pension funds, ignores the need for the father substitute. This is no small problem. It involves about 45,000 children in Great Britain—27,460 under local authorities and about 18,000 under voluntary bodies[1].

Unfortunately, most members of local public assistance committees and of philanthropic bodies have had no opportunity for acquiring even a bowing acquaintance with social biology. Yet, these same authorities to-day are often grappling with the vast problems of evacuation. Surely there is urgent need here for responsible advice and guidance if serious but avoidable war damage to children is to be prevented.

The Adolescent

Again, the personality develops at adolescence; the values and outlook then adopted will influence the youth and girl throughout life as citizen, marriage partner and parent; yet no systematic provision is made to explain the working of their own minds, bodies and emotions, to give them some idea of the interdependence of the different aspects of personality or to indicate how they may consciously integrate their own so as successfully to pursue a projected plan of life.

During the last ten years, as an emergency measure, about 100,000 of the 14–16 and 16–25 age groups have been given brief biological instructional courses on the place of sex in life, under the ægis of the more progressive local authorities and their youth committees by the British Social Hygiene Council, but what is that among the 6,571,800 young people of that age[2]?

What an opportunity is missed, too, in the administration of the National Health Insurance Acts, because our legislators and administrators did not appreciate their biological responsibilities!

Each year the young people leaving school for industry provide (supposedly) for their future health by registering under the Acts. In 1941 the age was lowered to fourteen and fifteen, the eligible entrants numbered 730,000, and these added their names to the medical men's panels. Unfortunately, under the name of 'health'—an ideal to be desired and striven for—only disease is paid for, or considered. The power to educate for health is in the preamble of the Act, but has never been implemented.

Social-Biological Problems

Knowledge of the effect of the endocrine equipment on character and behaviour has been available for years, but has not yet effectively influenced either our legal system or our moral judgments. In spite of the constructive work of the Institute for the Scientific Treatment of Delinquency, we still inflict prison sentences and label as recidivists many needing medical treatment and care.

No attempt has been made to relate new biological knowledge affecting man to our social values. This often results in social welfare and individual behaviour being at variance. Take, for example, society's attitude to health and disease. No teaching on the pyschology of the normal person—only the abnormal—is now included in the general medical training. Surely mental health is of paramount importance to the understanding of his patients' minds and emotions and is as essential to a medical practitioner as an understanding of their physiology and pathology.

Instead of a biologically minded community seeking the attainment of positive physical and mental health, and adapting the social structure to that attitude, there is a clash of values confronting the medical practitioner, which has seriously checked the application of science to man's development. As a social biologist the private practitioner should educate and work for the maintenance of health and the prevention of disease. As a citizen he must earn his living and maintain and educate his family. With our present knowledge of preventive medicine and our present form of medical organization, the two duties conflict.

Every professional barrier is raised to prevent medical practitioners taking an active part in popular health education; they in turn oppose every attempt at extending the field of preventive medicine through free clinics. The preventive early treatment of ailments and disease will, under the present system, reduce their means of livelihood. Even advice to the normal adult by competent lay people on preparation for, or adjustment within, marriage has been opposed by the medical profession, although the group of subjects concerned do not form part of ordinary medical training. Payments are made in relation to disease; the practitioner is not paid, as in ancient China, to keep his patients healthy. No community educated biologically would support a form of medical organization which created a vested interest in disease. That Western civilization has done so has undoubtedly been a factor in delaying the application of human and social biology.

It is cure of disease for which society pays and which therefore provides the large incomes.

Emotional and Intellectual Values in Conflict

One of the causes of the time-lag between knowledge and practice is the divergence between intellectually accepted truth and the traditional interpretation of spiritual or emotional values.

Although for two thousand years the statement that figs cannot be gathered from thistles has been repeated, had we applied the observation to man, and acted on it, we could have prevented the birth of many inherent defectives and increased the proportion of the genetically well endowed. The traditional opposition to selective parenthood persists. Emotional inhibitions have prevented the objective analysis and discussion of sterilization, limited even the discussion of entelegenesis to scientific journals, and buried in oblivion the interdepartmental report on abortion.

War conditions are directly affecting the number and quality of the coming generation, both born and unborn, yet no authoritative scientific guidance is available from those with real knowledge of the biological factors involved to those responsible for the mobilization and welfare of the man- and woman-power of the nation. It is urgent that existing knowledge should be reviewed and applied administratively to prevent ignorant good-will inflicting permanent genetic damage.

Young men and girls removed from home surroundings are marrying at short notice with no pre-marriage preparation or post-marriage help to adjustment. The result is a rising number of separation orders in 'war-marriages'. Some attempt is fortunately made by the Women's Services to keep marriage partners in touch, but no national policy in relation to the family is implemented.

Opposition to the use of vocational guidance arises from the widespread ignorance of biology. The effect on production and working efficiency of emotional anxieties is quite ignored, but is of serious import. The head of a training school for men between 19 and 21 reported that working efficiency had risen 10 per cent after courses of instruction relating to sex adjustment had been given.

The added personal responsibility deriving from the widespread knowledge and practice of contraceptives has altered personal values and necessitates constructive thinking. The increasing sense of parental responsibility accepts at a higher value the planning for a consciously desired child. The recognition of the value to individual development of both the play and the reproductive aspect of sex needs new social customs, new and personally accepted controls. A community seized of the truth of social biology will appreciate the impossibility of relating the spiritual and biological values of the 'unique relationship' in marriage, essential to full personal fulfilment, providing the required background for the child, and quite possibly an important instrument of human evolutionary advance, in a social structure that defers marriage until years after maturity, and for a large proportion of the population postpones parenthood beyond the optimum reproduction age. To-day, the emotional immaturity of the population and the absence of any attempt to relate new knowledge to emotionally accepted values in the field of personal and genetic progress limits emotional reactions in the mass to the primitive and childish. Hence the constant stimulus to irresponsible behaviour from commercially provided entertainment.

It is therefore of great moment that the proposed re-introduction of 'religious teaching' in the schools should take the form of an endeavour to inspire youth to rethink the traditional forms in which spiritual values are expressed; it is hoped authority will not seek to impose dogmas, but will clarify the truth they embody in a form that may go beyond, but would not conflict with, factual knowledge.

The dangerous ease with which false values may be presented to the intellectually ignorant in a for which will satisfy the mind and release the emotion drive is seen in Germany. The false values of aggressio and aggrandizement have followed the corre technique in the wrong direction, with the resulta chaos and disaster of a world war.

Science and Inspiration

There is a need to collate inspirational truth wit factual knowledge. Truth is expressed in man forms. The great religious leaders of the world hav proclaimed the facets of truth gained through intuitio and inspiration, in forms designed to appeal to th emotions. They have provided the positive philosophies of life that have been a major influence i dictating man's behaviour. Each inspired leader ha clothed his vision of truth in forms related to th knowledge and the social structure of the age i which he lived. Those religious systems that becom static and anchor 'truth' to the conditions of the ag in which they are formulated, die out; the ga between factual knowledge and religious teachin steadily increases—until the gulf between the emotional ideal and intellectual knowledge create divergent values, uncertainty of direction an ultimately, cleavage in personality.

Those religions that re-interpret the form an retain the spirit of intuitional inspiration are dynami and alive. Organized religion tends to oppose intellectual advance and takes refuge in an appeal t primitive emotion. This has probably been a important factor in prolonging the emotional childhood of man. On the other hand, workers in th field of science have tended to leave aside the real of values except as it affects them in common wit their fellow-citizens. Thus, when their views hav been expressed they are often accorded an authorit which they properly carry in their own subject, bu which they would be the last to claim in one the had not studied.

The Christian ethic asserts the unity of truth an the essential value of the individual personality. Th form has been constantly re-interpreted in the ligh of factual knowledge. The respect, for example, fo personality, which now takes a central position i its teaching, has only recently been interpreted a applying to women as well as men. A girl's marriag partner was arbitrarily chosen by her father, usuall on economic grounds, until quite recent times. Eve some bishops were polygamous up to the Middl Ages, and it is often forgotten that in an economicall ignorant world Church dignitaries opposed th abolition of slavery.

Values formulated from a small basis of factu knowledge, if unchallenged, retain their emotion appeal after discoveries and developments whic demonstrate their error have enriched the tradition intellectual inheritance; the old values become th prejudices of those who are too apathetic inte lectually and too fearful emotionally to challeng current interpretations. This is another factor in th time-lag.

The discoveries of the last three generations hav now created in living religions a dangerously wid gap between knowledge and practice, between inte lectual and emotional values, but that conscious an satisfying re-interpretation is possible can be demo strated by a personal experience.

Some years ago in India, it was my privilege t give a course of lectures on the development of th adolescent, to a large body of Hindu teachers. The span of years between the onset of the first physical signs of puberty and the attainment of physiological and psychological maturity was indicated. The Sarda Act was at that time before the country and the question of child marriage prominent in their minds. At the completion of the course, the chairman and members of the Teachers' Committee asked for a private conference. A number of pertinent physiological questions were put and answered factually and objectively. At the end, the chairman turned to his colleagues and said: "This is quite clear—we must have misinterpreted the Upanishads."

Social Biology in Administration

While man's further progress demands the projection of a unified and clarified ideal, there is no barrier other than that of the ignorance of the life sciences on the part of the responsible members of society to prevent the immediate application of much current biological knowledge that would promote human betterment.

Biology would appear to be of major importance to those responsible for leadership or who have jurisdiction over their fellows, at home or overseas—in Government and administration, the Church, the law, in the Defence Forces, industry, commerce and the social services. Yet, owing to present educational organization, it is among those who aspire to leadership that biological knowledge is conspicuously lacking. The majority of those seeking high office take the 'humanities' at the university. These are descriptive of the accomplishments of the mind and emotions of man—literature, history, language, but exclude the study of man himself as a living organism reacting to his environment, capable of the conscious integration of personality and responsible for the quality of posterity.

Dr. E. Lewis-Fanning carried out a small sampling inquiry in which "He extracted from the current Whitaker's Almanack, the names of the officers holding the rank of principal assistant secretary or a higher rank in various Government Departments. Of the 94 gentlemen in his sample, 42 were bred in the University of Oxford, 18 in Cambridge and 34 in some other or even in no university. We traced the academic careers of 40 of the 42 Oxford men and of the 18 Cambridge men. Of the Oxford men 31 took the School of Lit. Hum., 7 the School of Mod. History, 1 Mod. Hist. and Lit. Hum., 1 Jurisprudence and Lit. Hum. Of the Cambridge men 7 took the Classical Tripos, 5 the Mathematical Tripos, 1 each Natural Science, History or Law, 3 Mathematical and Natural Science, History or Law, 3 Mathematical and Natural Science Triposes. The sample is small, but a vocational bias of the humaner letters is indicated. Of the seven dignitaries in the War Office caught in Dr. Lewis-Fanning's sample, 5 had taken Firsts in Classical 'Greats'."[3]

A diplomat, administrator, politician or educator has at present no alternative but to become well acquainted with the biological sciences or to remain entirely ignorant of man's capacity to direct his own progress, so far as formal education is concerned, and is unequipped even to recognize the biological damage now often inflicted by social and administrative measures devised by the biologically ignorant.

We also have past errors to adjust. In recent reports on Colonial labour policies, stimulated by the International Labour Office, questions of social biology are constantly emerging. For example, the recent report of Major Orde Browne[4] describes the labour compounds of Northern Rhodesia and points out the human damage of these abnormal living conditions—a community preponderatingly male; such women as are present, are without their normal agricultural occupations and are passed on as temporary 'wives' from one man to another; the system encourages the spread of venereal disease and gives no stability for a family. But "the compound which admits of at least a proportion of married men is from every point of view preferable".

The malnutrition disclosed among the population of the fertile islands of the West Indies could not have persisted through three generations of general education had those in charge of administration, education and industry had an opportunity of sharing available biological knowledge. 'Education' had omitted any instruction or guidance in life or in the art of living. The cultivation, preparation and preservation of suitable food, use of local building materials, positive guidance in fitting the environment to the needs of man and the conscious development of man himself, all were ignored.

In 1939, with edible fish abounding in the surrounding seas, a population suffering from poverty and malnutrition paid for the import of 237,541 cwt. of canned fish[5].

Factual knowledge, without emotional development, cannot civilize the individual. While it is one of the assets of British secondary school education that 'character training' is an admitted objective, the type of character is that adapted to the British social structure. Colonizing governments have tended to transfer unadapted the educational system of the Mother Country to conditions overseas. Formal education is seen in its true colours in such new settings. It appears largely as a memory gymnastic, without influence on the man or woman as complete personalities. The facts memorized are unrelated to the emotional life or to traditional spiritual values; therefore, like discarded religious dogma, they have but little effect on behaviour. Such education tends to split rather than integrate the personality, to promote rather than resolve emotional conflicts.

For example, the deep-rooted and subconscious rhythm hunger of the African has been repressed, not drawn out and utilized, as a powerful aid to emotional development. This has had one peculiar result, with which I came in contact in Jamaica. Primitive African tribal dances can be seen and heard at dead of night in distant valleys or river beds—the rhythm of the music and the chant of the voices being African in cadence and tone. While the words, when analysed, are those of a Moody and Sankey hymn, the form and spirit of the dance are those of the African tribe. It is reported that primitive tortures have been inflicted under conditions of rhythm-ecstasy to enforce a local idea of Christian morality.

Again, the churches relate the 'value' of 'modesty' to the covering of the body with clothing, irrespective of skin colour, culture or climate. The West Indian is a practising Christian, therefore is fully clothed. The climate is tropical and heavy rain showers frequent. Many have no change for night clothing. In the old huts with mud floors the damp was absorbed; by the modern concrete floors it is not. Responsible local medical opinion recognizes this as one factor in the high tuberculosis rate. Another is the persistence of the deep-seated fear of the 'duppy' (the ghost spirit in bird form) which has been unresolved, because ignored, by education. Tradition decrees that all windows are hermetically sealed at night; however crowded the room.

It is only to be expected that in the West Indies to-day Major Orde Browne can report, "there is a lack of objective or purpose among young people nearing the end of their school days"[5].

The anthropologist and the psychologist need to co-operate with the educationist in designing the technique of cross-culture education.

Is it not urgent that those searching for truth in the laboratories and by observation and those experimenting in its application to man in the different parts of the world (now available) should be brought into close collaboration ? The discoveries of scientific workers and the experiences of administrators in India and the Empire would be of real value to the directors of education and to the youth committees of Great Britain. The collation of information and analysis of the problems would be facilitated by such a forum and study-circle as could be provided by an institute which had research in social biology as one of its active terms of reference.

Social Biology in Education

A serious factor in checking progress is the almost entire omission of human or social biology in the curricula of British universities, teachers' training colleges and schools. It is claimed that the younger generation are better placed to rethink values as they are less influenced by current prejudice, and recently acquired intellectual knowledge is more vivid. It is therefore vital that youth should be equipped with all available factual knowledge that bears on man himself and his potential development if their philosophy of life is to embody the nearest present perceivable approximation to truth.

Without a minimum of general understanding of biological principles, such discoveries as are made find no receptive public ; there is no general critical and knowledgeable body of opinion to relate new facts to existing problems, and no appreciation of the value to man of the progress made possible by the efforts of the scientific worker; hence the absence of financial and social recognition for the biologist.

Funds have in recent years been available for research in agricultural biology in the interest of the farmer, the stock breeder, the poulterer and the gardener ; but so far neither Governments nor individuals have come forward to encourage and subsidize research and observational experiment on man himself. The outstanding exception is Sir Francis Galton, who endowed the only chair of eugenics in Great Britain, now held by Prof. R. A. Fisher. The Weldon chair of biometry, now held by Prof. J. B. S. Haldane, is unfortunately limited by the proviso of the trust to "the higher statistical study of biological problems".

Research fellowships and studentships provided by bequest, trusts, and industry abound for physics, chemistry, engineering and the arts ; but in universities those reserved especially for the study of man as a social biological unit can be numbered on the fingers of one hand.

An analysis of the distribution of exhibitions, scholarships, studentships, fellowships, prizes and medals, from four universities, recently made by Dr. I. Frost, discloses that in a total of 346, three go to genetics or psychology, one to social psychology and ten to physiology. Fortunately, there are forty-three awards open to any subject, so that, as interest in those subjects affecting man attract the outstanding students, work in human and social biology can receive encouragement[6].

At present a degree in biological science at a university has to be in zoology, botany or the more specialized biological subjects such as medicine, agriculture, etc. There is no university course in social or human biology, while certain university courses in social science still ignore the subject. That this practice does in fact deflect attention from, rather than to, 'man' is shown by a demonstrator in zoology at a well-known university who deplored the lack of opportunity for the consideration of the human in his teaching and was told by his professor that he was "very daring" to use the human skeleton as a demonstration subject, and that it was "too dangerous" for him to include the human skull—this was 1941 not 1641. Under these conditions, a feeling has arisen among some zoologists and botanists that problems relating to man and his adjustment to environment are outside their purview.

At the end of last century and at the beginning of this, physics and chemistry had a struggle with the arts for *Lebensraum* in general education. The last few years have seen biology struggling with the other sciences for a share of the limited school time allotted to science. Educationists are still far from realizing that a general knowledge by pupil and teacher of the normal characteristics of man himself and some appreciation of the art of living should be fundamental to all education.

Social biology provides the basis for personal health and social relationships, and would enable a responsible democracy to create a social structure designed to enable man to attain his potential mental, emotional and physical stature. It was from the Empire and India that came the first appreciation of its importance. A special conference was held in connexion with the Imperial Social Hygiene Congress of 1930 from which memoranda, urging the introduction of the biological sciences to Colonial education, were transmitted to the Colonial Education Conference and to the Colonial Office Advisory Committee on Education. These representations were later supported before the Committee by Dr. W. K. Spencer and Prof. Julian Huxley and resulted in Prof. Huxley's tour of the African colonies. His subsequent report to the Government on "Biology and the Biological Approach to Native Education in Africa", and the publication of "African View", together with Margery Perham's outstanding work, marked real progress. The way was prepared for the guide to Colonial development provided by Lord Hailey's "African Survey".

In 1932 the then Prime Minister appointed a Committee on "The Education and Supply of Biologists", in which the importance of introducing the subject in home education was emphasized. The Hadow and Spens Reports brought science and the education of the adolescent under review. Authority now gives encouragement to nature study and biology but still hesitates to direct the attention of youth to the study of man and mankind as emphasized by Mr. L. J. F. Brimble in a recent address[7]. Of those who advance so far, many still believe that provided something be taught in school about man's capacity to breathe air and digest food, the major responsibilities, namely, those of reproduction and the integration of man's own personality, can be ignored.

In 1932 also, the National Conference on the Place of Biology in Education drew together educationists and biologists, who fully ventilated the question. A similar conference followed in Scotland. The Education Advisory Board of the British Social Hygiene Council gave permanent form to the movement. It has for nine years pressed the claim, first for time for general biology in the school curriculum, then that the biology taught should relate to man and extend to social biology.

Syllabuses for three alternative approaches up to School Certificate standard were prepared: from a basis of nature study, by Sir Arthur Thomson; from a basis of hygiene and physiology, by Prof. Winifred Cullis; and from general science, by Prof. Julian Huxley.

The results of the various efforts are reflected in the steady increase in biology shown by the School Certificate returns:

School Certificates

All Schools in England and Wales.

	1933	1934	1935	1936	1937	1938	1939–40
Biology ...	6,179	7,383	9,968	13,467	15,111	15,852	15,602
	9%	11%	14%	18%	20%	21%	22%
General Science	2,560	2,842	3,204	4,156	4,771	8,784	13,465
	4%	4%	5%	6%	6%	11%	19%

In the present emergency the demand is growing from teachers and education authorities for refresher courses on human biology and for short courses for 'school leavers' on simple social biology, but the need and the urgency is beyond present resources.

Under war conditions teachers of evacuated schools have many additional demands on their time and good will from the out-of-school needs of their pupils; some guidance to them on problems of psychology and social biology is badly needed.

Interest in social biology as applied to education is growing rapidly and war conditions demand effective action.

An attempt has been made to present a few practical instances, drawn from home and overseas, of failure to use existing knowledge, of lack of opportunity for those working in different fields to exchange experience, of opportunities missed for the application of biology to human welfare. The war effort is handicapped by man's emotional immaturity and biological ignorance.

It is suggested that a central organization for social biology should be inaugurated and that its first step now should be to evaluate existing knowledge and to consider methods of its application to current problems. The second, to invite the attention of universities, research councils, institutes and Government departments to questions meriting immediate research, observation and inquiry. The third, to promote constructive discussion in the re-interpretation of our social and spiritual values. The fourth, to act as a consultant body to governments, local authorities and professional bodies. The fifth, to provide information to responsible persons and to promote post-graduate teaching.

A number of groups are already interested in or concerned with application and research in one or more branches of human and social biology. For example, the departments of physiology, psychology and anthropology at the universities, the Medical Research Council, the National Institute of Social and Economic Research, the Royal Anthropological Institute, the Rockefeller International Board and certain philanthropic trusts.

In the practical application of social biology, the Eugenics Society, the Child Guidance Council, the Institute for the Scientific Study of Delinquency, the Nutrition Society, the British Social Hygiene Council, etc., are all doing a certain amount of the kind of work which should be given wider scope.

Concerned in the administrative measures with biological implications are the local authorities, through public health, education, public assistance and evacuation, magistrates, lawyers, probation officers, the medical profession and various departments of government.

Responsible for guiding public opinion are the Press, the Church, the educationists and the writers.

In Great Britain, a pioneer effort of a voluntary character has been the precursor of most national developments: from Drake and his privateers to the British Navy; from the Church schools to general compulsory education; from the friendly societies to National Health Insurance. A central organization having social and human biology within its purview might well blaze the trail for a national administration consciously directed to the improvement of human quality.

A national conference could, in the first instance, be convened to which all concerned would be invited in their individual capacities. The object would be the formation of an organization which would include the scientific worker in social biology and other social sciences at home and overseas, together with administrators and leaders in those fields affecting personal and social welfare. The sessions of the conference would be planned to summarize accepted factual knowledge, to indicate researches already perceived as desirable which could be promoted under responsible auspices and to stimulate the development of a positive philosophy of life satisfying to both intellect and emotions, embodying the ideal of man consciously directing his own progressive evolution.

From the conference, a small and active provisional executive could be charged with the task of appointing working committees, of forming a representative governing body, of seeking funds and of making initial plans for the co-ordination and presentation of research. In the case of social biology, consultative groups should be brought into existence without delay to advise on problems of emotional development and guidance, evacuation, juvenile delinquency, the care of the abnormal and sub-normal, preparation for marriage and marriage adjustment.

A panel of qualified lecturers would offer elementary and post-graduate courses in the social sciences; for example, in the case of social biology they could be offered to Civil servants and local authority officials and members, to magistrates and lawyers, to medical practitioners and the allied medical services.

Qualified lecturers could be nominated by the organization to participate in social science and other courses provided by the universities.

The committees concerned with research, with practice and with ethics would be in a position to submit questions needing analysis, observation or inquiry to the existing organizations equipped either to finance or to undertake the tasks.

Large funds for new enterprises, except for those directly related to war, or immediate post-war problems, could not be sought; but where the application of existing knowledge could materially increase the efficiency or reduce the human damage of the war effort—either safeguard or improve present or future human quality of physique, intelligence and character in the population—immediate action could be called for.

A number of the services suggested could be offered on an economically self-supporting basis.

To desire and seek truth and embody its wisdom in a plan of life is surely an ideal which will call out man's highest endeavour.

IMPACT OF THE PHYSICAL SCIENCES ON SOCIETY

By Prof. J. A. CROWTHER

University of Reading

THE *cause célèbre* of the Inquisition *v.* Galileo Galilei has often found mention in the columns of NATURE. In every recrudescence of the old controversy between science and religion it is as certain to crop up as King Charles's head in Mr. Dick's memorial, or as the burning of coffee berries at Costa Rica in a certain type of political argument, and with about equal relevance. The opprobrium showered on the instigators of that famous trial has been, perhaps, somewhat excessive. Their methods must be condemned—truth is not to be suppressed—but in their recognition that scientific discovery raises problems of vital import to society as a whole the Jesuit Fathers showed an insight into the potentialities of science which it would have been well if it had been shared by the statesmen of the past hundred years or so. The impact of discoveries in the physical sciences upon a society unprepared to receive them has led to an enormous increase in material wealth, but at the same time has raised a host of social, economic and political troubles from which the world is suffering to-day.

Though deplorable, it is not surprising that the far-reaching consequences of the work of the natural philosopher were not foreseen either by philosopher or politician. In spite of the often repeated statements to the contrary from upholders of a certain political philosophy, the discoveries in physics which have done most to change the face of society were not made with the conscious desire of meeting the material needs of mankind. Michael Faraday did not begin the researches which led to the discovery of electro-magnetic induction and issued in the present electrical era, in an attempt to improve on the Bunsen cell, nor did Sir J. J. Thomson discover the electron with the object of enabling the world to listen in to the B.B.C. Without in any way depreciating the painstaking and often brilliant work of the applied physicist, who, for very little reward, harnesses the principles of physics to the benefit—or destruction—of mankind, it remains true that the great revolutionary advances have been made by men who have had no motive except the undowered pursuit of truth in the natural world. The man who seeks for the love of the search will discover more than a man who is just looking for his collar-stud. Paradoxically enough, the first requisite for any further great progress in the application of science to the welfare of society is that the man of science shall be able to pursue his researches in absolute freedom from economic motive or State direction. Science in fetters will ultimately fail even in its ancillary duties as the handmaid of industry.

This being so, it is important if the disadvantages of the *laisser-faire* policy of the past are not to be perpetuated, that steps be taken now in preparation for dealing with the discoveries pregnant with new possibilities which are sure to come along. Research is always most difficult, though often most rewarding, in the no-man's-land which lies between the different sciences. It is likely to prove exceptionally difficult when the sciences differ as widely as physics and sociology: yet a liaison between the two is the most hopeful way of ensuring that the vast potentialities which the physicist is ever laying bare should be utilized for the welfare, and not to the hurt, of mankind. There is inevitably a pause, longer or shorter, between the discovery of a new principle, and its application. It is in this interval that direction and control can most easily be exercised. An excellent example of an opportunity happily grasped in time is provided in the control of broadcasting in Great Britain by the creation of the British Broadcasting Corporation. Instances where the opportunity was not seized may be left to the reader's own judgment.

The problems facing any central organization for sociological research are not, however, merely those of procuring a greater use of the unfolding powers revealed by the physicist. There are some possibilities which it might be wiser not to develop, and others where the application might be wisely delayed until necessary adjustments in our social organization had been made. An illustration, on a small scale, is provided by modern traffic conditions in our great cities. It is reported that the late Marquis of Salisbury would order his carriage and pair to await him in Downing Street ten minutes before his train for Hatfield was due out at King's Cross. It is doubtful whether a Secretary for Foreign Affairs just before the War could have cut the time of the journey so fine, although his modern car had some ten times the top speed of the Marquis's equipage. A more serious example of 'bad-timing' is provided by the whole history of the industrial era.

Almost every material problem is essentially a question of the proper utilization of energy; and practically every payment we make is directly or indirectly a payment for energy. Matter itself is indestructible, and though not unlimited in quantity, more than ample for our needs. Man's ability to gratify his desires on the material plane is limited only by the energy which he can control. It is for this reason that physics, which is the science concerned with the study of energy in all its protean forms, has played so large a part in the material developments of the past hundred and fifty years. Until the beginning of the scientific era man had to rely for his supply of energy mainly on his own body, aided by that of domestic animals and to some extent by wind and water. The advantage of the human body as a machine is, of course, its infinite adaptability. There are still, and probably always will be, operations for which its unique co-ordination of mind and movement is essential. The disadvantage is its running expenses, which, compared with other forms of energy, are very high. Electrical energy equivalent to that which a man can produce can be had for a copper or so a day. Steam-power, on a large scale, is even cheaper. Unless a man's time is worth less than a penny or so an hour any mechanical operation which a machine can be designed to carry out can be performed much more economically by the use of one or other of the newly discovered forms of energy. Therein lies the explanation of the enormous increase in material wealth since the beginning of the so-called industrial era. It has been estimated that the average citizen of the United States was, just before the War, enjoying amenities equivalent to those which in classical times would have demanded the services of thirty slaves. There is no reason to suppose that the process has reached or even approached its limits.

There is, as everyone knows, a reverse side to this encouraging picture. The scrapping of obsolescent machinery is economically sound, but if the machine happens also to be a man the results are extremely distressing. It is perfectly true that on the balance and over a period of time the introduction of scientific sources of energy has found employment for far more workers than it has displaced. New physical discoveries have formed the basis of great new industries, and more workers with a far higher average output are now employed than ever before. The change-over period is, however, bound to cause intense suffering, unless the changes can be foreseen, and plans worked out to ease the transition. Only by constant and co-operative study and research can this be ensured.

The introduction of new forms of energy has, moreover, introduced more permanent changes into the structure of society. When each worker was his own power unit his work could be carried on effectively anywhere. Those were the days of the master craftsman, and a man could be, and frequently was, his own master. Steam-power, the first to be introduced, requires for its most economical application to be generated in large units. Moreover, the prime cost of installation was high. Workers had to go to the machine, and the factory system sprang into being. The early evils associated with that system have been largely eliminated, partly by enlightened legislation, partly by the gradual realization, as a result of psychological research, that dismal and unhealthy conditions of working are inimical to high output. A modern factory compares very favourably in its amenities with the average university research laboratory. The scale of living of the factory worker to-day is far higher than that of the home producer of a hundred years ago, while owing to ancillary scientific inventions such as the radio, the cinema, and quick cheap transport his facilities for enjoyment have been greatly enhanced; and owing to cheap energy his hours of work reduced. So much lies on the credit side; and, as I have said before, the limit has not yet been reached.

If, however, we believe that man does not live by bread alone, not even by bread and circuses, there may be another side to the question which at least merits investigation. What, if any, has been the effect on the men concerned of transforming a number of at any rate semi-independent skilled artisans into a body of factory operatives? Assuming with Ruskin (a much discredited writer whom, I am told, few read to-day) that the true wealth of a nation lies in the quality of its individual citizens rather than in the mass of its material possessions, how does say five or six hours a day (supposing factory hours to be reduced to that number as they easily might be) spent in tending three or four automatic machines, or in any of the monotonous and mindless operations of a mass-production plant compare, from that point of view, with a somewhat longer daily period spent in an occupation where hand and brain are harmoniously employed together in the production of a finished article? Some preliminary research on these matters has been begun. Much more is needed. I would only add that should some decentralization prove to be desirable from a human point of view, the facilities are available to effect the transition without too great a loss of output. The transformation of steam into electrical energy has made the distribution of cheap energy to small production units an economically sound proposition.

The plea for the wider application of science in social affairs is often presented as if it were merely a matter of more research, and a fuller application of the results of research in everyday life. In the case of the biological sciences, from which direction the pressure mainly comes, this is undoubtedly true. Freedom from disease, an ample sufficiency of good food, and appropriate clothing are fundamental necessities, and the biologists do well to insist on their ability to satisfy them. One would like to define the task of the physical sciences as the liberation of man from drudgery, so that he might be free to develop and enjoy his higher faculties, of which his creative ability is not the least. Owing to the, perhaps not unnatural, emphasis which has been placed on the accumulation of material wealth, it is doubtful whether the sum total of the drudgery of the world, of labour in which it is impossible to take either joy or pride, has been substantially reduced, though hours of work have been lessened, and can be still further reduced as the potentialities of physical research are more fully applied.

It would, I think, be an error to suppose that under any system of planning the volume of fundamental discovery in physical science could have been much increased, or the pace of its application to social purposes profitably accelerated. It is direction rather than speed which has been lacking. New powers have been exploited without a full consideration of their remoter repercussions upon society. To take perhaps an extreme but poignant example, the destruction of the heart of Coventry was implicit in those few brief seconds for which the first aeroplane lifted itself from the ground, but no warning was given, or at any rate was not heeded until too late.

The question of what constitutes 'the good life', is one of philosophy and religion, not of science. A wise society will take from the treasure house of science whatever it needs for the furtherance of its purposes, leaving unexploited, or at any rate severely controlled, what might be harmful. Society, however, needs, and is entitled to, the best advice on the more immediate, and the more distant consequences of the use, or neglect, of the opportunities provided by scientific discovery. Neither physicist, economist, nor sociologist is competent alone for this task. A combination of the three might do much to direct the stream of progress into the happiest channels.

SOCIAL SCIENCE, STATISTICS AND POPULATION PROBLEMS

By D. CARADOG JONES

School of Social Sciences and Administration, University of Liverpool

THE vice-chancellor of one of our modern universities has been heard to state on more than one occasion that he has failed to discover what is meant by social science. In a lesser man that might be taken as lack of appreciation of a field of knowledge fraught with immense consequences to mankind; but in this case it was no doubt intended as a criticism of social scientists because they have not defined with any precision the boundaries between their own and other sciences. That is not surprising in view of the rapid development of interest in the study of sociology. Interpreted widely, as it should be, it would include any branch of knowledge concerning man regarded as a social animal, in short, the study of human groups. Although, for convenience of observation, individuals may be isolated, interest centres in their social behaviour, their relationship to other individuals similar in many respects to themselves. But the diversity between them, in temperament, in outlook, in aims, is of even greater importance than the likeness. It is these differences, if not delicately handled, that produce strains and ruptures—strikes, wars and revolutions—in the body politic. There is an attraction in superficial remedies for such conditions, but they do not last. We spend our energy too often upon the perfecting of the machinery of social life, while neglecting the source and spring of all motivization: it is like designing a car, stream-lined and beautiful in all its parts, only to find that we have no suitable fuel to make it run smoothly. One of the most fundamental of the social sciences is psychology, because it explores the nature and causes of the divergences between individuals in their innermost citadel where they are most intimately revealed.

Another fundamental social science is philosophy, which creates harmony out of an assembly of seemingly discordant voices. This is achieved by discovering the purpose of life and so relating a diversity of means to a single-minded end. The individual converted, the right leader found, it can turn a mob into a disciplined army; but the purpose of the army is not to wage war upon some other faction. This social philosophy is essentially moral: it takes all the world as its parish, for in the realm of science there can be no partisanship. The warfare will not be against flesh and blood, but against ignorance and disease of mind and body, a ceaseless campaign systematically waged to get the best out of the rich natural resources available for the well-being of all mankind.

Assuming the philosopher to have contributed his share to the shaping of the new world, the political scientist will next be called upon to design regional and international instruments capable of transmuting the philosopher's ideal plan into realized fact; the public administrator will assume responsibility for the right use and control of these instruments; and jurists will codify agreed rules to regulate social behaviour. As the curtain unfolds, the stage is seen to be set for actors almost without number, and each must play his part. The social historian warns us against the purchase of experience at too dear a price; he would have us profit by the mistakes committed in the past. The geographer deals with the reactions of human groups to their environment; it is his task to make an inventory of the raw materials latent in land and sea, to consider the most profitable use to be made of them, and to determine whether some areas are not too densely packed in view of their resources while others are starved of people to develop them adequately. Problems concerning the distribution and exchange of commodities come within the province of the economist; while the town planner contrives to apportion the land wisely to different uses, thereby preventing that haphazard building which has so frequently distorted the natural beauty of the countryside.

Hitherto we have failed to make a success of world government, not because we have lacked experts in all the social sciences mentioned, but because it has been nobody's business to survey the world as a whole and to co-ordinate the activities of these experts so that they work to a common plan. There has been another reason for failure: we have interpreted wealth in material terms and not in terms of human satisfaction. Economists and statisticians must take their share of the blame because, in comparing the standard of living of one class with another or the national income of one country with another, they have used money value as their measuring rod—with this much justification, that it seemed to be the only means of accurate measurement to hand. Yet, taken alone, it can be but a very imperfect index of what is really valuable in life. If we are to take true stock of a country's wealth, should we not start with the people who inhabit it? Apart from them, no other kind of wealth has sense or meaning.

So far this review has been in general terms. When we come down to practical details, we quickly discover large gaps in our machinery for making a satisfactory survey of the resources of even a small part of our own Empire, leaving other countries out of the account. Yet, to undertake such a continuous survey should be one of the main functions of the social scientist. Acting on the principle already enunciated, the most important feature of this stock-taking would be to trace the trend of population, in size and character. It was well known before the present War began that the population of Great Britain, in common with that of most other European countries, was fast approaching a decline, and the War itself will have gravely aggravated this condition. But population must always be considered in relation to the area occupied and to the stage of culture reached. With that in mind, the question arises—How shall optimum population be defined? And, having defined it, how shall it be achieved and how maintained? Clearly the optimum is not merely a matter of size. More important than their number is the quality of the people who inhabit any country. But quality varies from class to class, from individual to individual, and even from age to age in the same individual. Hence, as a first step towards a definition of the optimum, it would be well to try to assess the size and quality of the actual population at some given date, and to measure the effect upon it of a changing environment. Until such periodical assessments can be made over a sufficient interval of time, we shall be working to a large extent in the dark, lacking any standards or axis of reference.

How far do we take stock of the human wealth of the nation at present? The census provides us with a reasonably accurate count of the people every ten years, and enables us to classify them by location and by households. The population can also be split up into age groups, by sex, marriage condition and occupation. This gives us a photographic record at the date when the count is taken. In addition, day by day during intercensal periods, there is a legal obligation to register every new birth, marriage and death, and very few, in fact, escape registration. But, wasteful as it seems, these records have hitherto been kept in isolation from each other and from the census returns. There are, no doubt, administrative and other difficulties in linking them together, but these should not prove insuperable tasks.

Since every marriage starts a new family, the potential source of new wealth, and birth represents the actual creation, while death is the destruction, of human wealth, the State should keep as complete an account of these vitally important events as any efficient business firm does of its gain or loss of material goods, and should relate them to one another. This could be accomplished if, at every registration of a marriage or death, the law required the production of copies of the birth certificates of the persons concerned, and at every registration of a birth the production of a copy of the civil registration of marriage. It would be possible then to start a card index of each family at its foundation on marriage, and to keep it up to date by adding fresh records of birth, marriage or death as they occurred, until each member of the family, parents and children, passed out by death or started a new card by marriage.

The family, though the smallest, is undeniably the most important unit of social life, and these family cards, when analysed by random samples—drawn from different districts, or from different occupational groups determined by the occupation of the head of the household—would provide a rich mine of research material for students of social science. Important differences in marriage tendency, in fertility, in the incidence of mortality would come to light, and we should be in a much better position than we are now to say which sections of the community are contributing most and which least to the population of the future. Associated with individual identity-cards, such a scientific registration scheme could be used also to keep track of movement from one region to another, and of migration into and out of the country, as does the admirable system of registration which has been in use for some years in Sweden. No names, of course, would be disclosed; the material would be used solely for administrative and research purposes.

Periodical surveys should also be made of random samples of different classes of the population, in order to determine what is representative of each class—and the amount of variation from the average—in physique, nutrition, health, intelligence, temperament, character. In war-time the need for a detailed examination of the physique and health of all applicants to join the services is recognized as imperative. The need is no less in times of peace, but any such medical inspection is then confined in general to children of school age and those who take up certain types of occupation. In the task of establishing authoritative standards or norms of physique, nutrition, and health, by the analysis of selected random samples, the statistician will have to lend his aid to specialists in health and nutrition.

When we go on to consider the measurement of intelligence, our difficulties increase. The more important the quality to be measured, the less satisfactory are our instruments for the purpose. Some headway has been made in devising intelligence tests for the young, and we can certainly start by making as complete a survey as possible of the rising generation. But considerable research is still needed before we discover satisfactory devices for the assessment of temperament and character. Yet it is only when we reach the stage of trying to measure any such characteristic, however imperfectly, that we find ourselves impelled to seek to understand its true meaning and to define it in terms free from ambiguity.

Stress has been laid in this article on the importance of taking periodical stock of the population, because it is mainly in the people that the interest of the social scientist lies. But the people express themselves in their institutions and in what they make and do, so that our national stock-taking would be incomplete without a survey of all other forms of wealth. This opens up still wider vistas for investigation. The young hold the key to the future; we must therefore examine whether our educational system is such that we make the best use of the human material at our disposal. Pushing the inquiry further back—Is the training given to our teachers the most suitable for its purpose, and are they chosen in the best possible way? There is urgent need also to ask why, as man's capacity to produce grows, industrial depressions are intensified. What are the frustrations which prevent the free flow and exchange of goods and services? Are the ruling factors economic, dependent upon the improper adaptation of money to its purpose and the unwise handling of facilities for the creation of credit, or are they associated with selfishness, the power of monopoly and vested interests, possibly misguided even from the point of view of their own self-interest? Again, as opportunity for rest and recreation increases, are we learning to use it to better advantage? Under a machine economy the pace of work and of living generally is vastly accelerated. How is rest for the mind and for the nervous system to be obtained? Are these questions that can be settled by the medical man only or have they a psychological or spiritual basis?

So wide and intricate are the problems involved in any survey on the scale contemplated that the co-operation of experts in many fields would be essential to unravel them. A central research institute, if of independent status like a university, and adequately financed, would undoubtedly attract the services of distinguished men of science. It should have a permanent staff; but it should be able to enlist also the aid of other social scientists, whether in universities or associated with such bodies as have already been founded by private benefaction for the purpose of social research. In order to prevent overlapping and to secure comparability of results in all such inquiries, it would be the function of the central institute to encourage co-ordination and concerted planning. Along these lines it should be possible in due course not only to ascertain the value of our possessions but also to get some idea of the potential capacity of our people, and thereby to raise the general standard of living and national culture to a much higher level than we have yet achieved.

ETHICAL AND POLITICAL REMODELLING OF SOCIETY

By SIR FREDERIC KENYON, G.B.E., K.C.B., F.B.A.

THE rehabilitation of a wrecked and bewildered world will be the task of the years which lie immediately before us. In 1919 we hoped that we might restore the world as it was before 1914, with additional provision for its security. In 1942 we know that that attempt failed, and that when the present threat to civilization has been defeated it will be necessary not to restore an old world but to lay the foundations of a new one. A movement which has been in progress for a generation has been greatly accelerated. The foundations of society have been broken up. A new outlook on social relations has become necessary, and we have to orient ourselves in the new circumstances.

Up to the outbreak of the War of 1914–18 we were in effect living on the Liberal philosophy and political economy of the middle of the nineteenth century. Its corner-stones were individualism, *laisser-faire* and free trade; its prophets were Mill, Herbert Spencer, Fawcett. The State should interfere as little as possible. The individual should be left to develop in his own way; to buy in the cheapest market and sell in the dearest; to aim at material welfare and let the devil take the hindmost. It was a philosophy unimpeachable if once you accepted its fundamental axiom, that the whole duty of man is to cultivate material prosperity. Its best exponents recognized that the 'economic man', for whose conduct they enunciated principles, was not necessarily the whole man; but the politicians and the popularizers of scientific thought ignored this qualification, and for some three generations these doctrines governed the thought and the political practice of the nation.

There were always some—Carlyle, Ruskin and the Christian Socialists notably—who combated a political economy which they accused of being soulless. There were always some who maintained that, while unrestrained individualism was good for the strong and might bring wealth to a State, it involved unjustifiable suffering for the weak. A sense of social responsibility began to grow, and took visible form in the 'eighties, in such movements as the Salvation Army and the foundation of university settlements. Gradually, almost unconsciously, the State and the local administrations accepted more and more responsibility for the welfare of the people. The 'social services' assumed an ever-increasing importance in national and local budgets, which meant in fact that the larger incomes were curtailed for the benefit of the smaller. The War of 1914–18 intensified this movement; it gathered strength in the uneasy years of peace from 1918 until 1939; and with the new War it has come with a rush. The State has assumed control of nearly every form of activity. Large incomes are taxed to the verge of extinction. Hundreds of millions are drawn from the profits of individuals and companies and applied to keeping down prices for the poorer classes and increasing their earnings. The exigencies of war have brought us to accept, almost overnight and without a struggle, an almost complete measure of national socialism, and a very extensive levelling up and down of incomes. The problem now before us is, how much of this remodelling of society should and could be carried forward into the years of peace which will follow when once the forces of evil, with which we are engaged in a death-struggle, have been overcome.

The great danger is lest this problem should be approached under the old forms of political controversy, with the leaders of each party striving to stake out claims for those whom they represent, and to turn to their material advantage the opportunities of the moment. This, by whatever party it is practised —employer or employed, capital or labour, the 'haves' or the 'have-nots'—is war profiteering, the turning of the exigencies of war to one's own material profit. It may be more justifiable on one side than on the other; but the basis is the same, the nineteenth-century doctrine that everyone should do the best he can for his own material advantage.

The remedy needed is something far more fundamental. We have been so saturated with the doctrine that material welfare is the prime aim of life that we do not realize that it has not always been so. Material welfare has, no doubt, always been a motive of human action, and often a powerful one, but it has by no means always been the predominant one. It has not always been held that man lives for bread alone, or that "they should take who have the power, and they should keep who can". We know now to what the unrestricted application of this doctrine has led us. We want now to reconsider its validity, objectively and impartially, and to determine how it can be improved or replaced.

We want, in fact, a new political philosophy; and in this phrase the epithet is not used in the restricted sense of parliamentary and municipal controversies, "where ignorant armies clash by night", but in the sense in which "politics" means the art of living together in a civilized and organized community. This art has to be thought out afresh, and the thought needs to be as unimpassioned as possible. It is also of the first importance that the thinking and the formulating of its results should be done without delay, in order that the field may not be pre-occupied by the combatant politicians (in the narrower sense), and that the results of dispassionate thought may be at the service of the statesmen who eventually have to lead the reconstruction of our national life.

It is for this reason that the establishment of some form of central organization of sociology seems to many persons to be a desideratum. Just as the Institute of International Affairs serves a useful purpose in the collection of facts and the formation of opinion on international matters, and as institutes of archæology or chemistry or chartered accountancy bring together those who are interested in these subjects for the interchange of views, so a similar organization for sociology would serve as a forum for the formation of the new philosophy of social relations which seems to be needed. This is not so unpractical a proposal as it may seem to those who are satisfied with the limited vision of immediate controversy. It does not mean that long-bearded and unpractical scholars will sit down to elaborate paper constitutions or new Utopias. It means rather that those who are engaged in social activities will pool their experiences, will be invited to formulate their principles, and will be encouraged to work on a basis of co-operation rather than controversy, to see how much harmony can be achieved, not how much can be seized by force from an unwilling opponent.

For the operations of such an organization some guidance can be derived (as in so many other provinces of thought and science) from the Greeks. For Plato and Aristotle and their followers ethics and politics were intimately connected. The virtues of the State were the virtues of the individual, writ large. The social and political ideal of Aristotle is thus expressed by Mr. W. L. Newman:

"The State exists for the exercise of the qualities which make men good husbands, fathers and heads of households, good soldiers and citizens, good men of science and philosophers. When the State by its education and laws written and unwritten succeeds in evoking and maintaining in vigorous activity a life rich in noble aims and deeds, then and not till then has it fully attained the end for which it exists. The ideal State is that which adds to adequate material advantages the noblest gifts of intellect and character, and the will to live for their exercise in every relation of life, and whose education, institutions and law are such as to develop these gifts and call them into full play."

It is indeed the restoration of the connexion between ethics and politics that must be the principal aim of the new social philosophy. The whole tendency of political thought in the nineteenth century was to divorce them. Religion was excluded from the education given by the State, because religious dissensions divided the people so deeply. The current political economy deliberately excluded moral considerations, in order to concentrate on purely material considerations. In every department of life, in art and literature no less than in economics and politics, the intrusion of morality or religion was resisted. The economic man, not the ethical man, was made the basis of political theory, and material wealth was the goal of political practice.

The last hundred years have seen these principles tried out, and we are now in a position to estimate the result—a considerable amount of material success, leading to a moral *débâcle*. It would be the task of the organization proposed to study how the good can be separated from the bad; how freedom of the individual in thought and action can be made compatible with justice to all; how individual initiative can be encouraged without exploitation of the less fortunate masses; how the standard of life can be raised for the many without forfeiting the benefit which the whole community receives from the exceptional abilities of the few. We have been told that civilization has become mechanized; what it needs is to become moralized. We have before us terrible examples of the results of totalitarian control unrestrained by morality. We can see its efficiency, and we can also see its demoralizing effects. The new political philosophy must aim at securing the first without incurring the second; and this can only be achieved by the objective and dispassionate thought which an organization for sociology would cultivate.

We cannot afford to wait for an individual to give us the guidance which we need. If such a genius should appear, to be the Adam Smith or the John Stuart Mill of a new generation, it would be a godsend; but the need is urgent, and the ground can at least be prepared by co-operative effort. From such effort we may hope to obtain that philosophy of human affairs which Socrates, twenty-three centuries ago, declared to be necessary for the right conduct of life.

RESEARCH IN THE HISTORY OF SOCIOLOGY

By ALEXANDER FARQUHARSON

General Secretary, Institute of Sociology

IN any discussion upon the better organization of research in the social sciences in Great Britain the question of the place to be assigned to historical research will inevitably arise. This article leaves on one side the problems of the general development of research in social, economic and cultural history, and considers only the need for research in the history of the scientific study of society. The intimate connexion between that history and the general history of thought and of science will not be forgotten.

The history of the scientific study of society may be conceived in a wider or narrower sense. At its widest it may be taken as including all attempts throughout the history of mankind to present a systematic and consistent picture of the structure and development of particular societies and of groupings of such societies up to the limits of the known world. The work of Herodotus in the Hellenic world, of Ibn Khaldun in the Moslem world, and of Lord Hailey and his colleagues in the recent "Africa Survey"—to take three handy examples only—would fall under this definition. Research might deal with such topics as methods used (personal observation, second- or third-hand report, forms of record), models followed, the debt of each worker to what went before, a comparative study of interpretations of phenomena recorded.

A great part, however, of the work to be done would be in a field already occupied by historians as students of methods used and interpretations adopted in historical studies. An account of a society at a particular moment of time in the past has in general already won recognition as a source for its history, and in many cases has been subjected to an intensive critical examination[1]. Further, there already exist general critical accounts of such sources for particular epochs and territories, and also general accounts of the development of historical studies, the accumulation of material for these, and the growth of historical method.

The impossibility of separating the 'static' and 'dynamic' views of society becomes even clearer when pre-history and archæology are considered. The same material remains must be used in reconstructing either a picture of social conditions at a moment in the past or a panorama of social development from stage to stage. Further, this wider history must take account of theories of society, from Aristotle to Toynbee, and the critical work already expended on these by historians, philosophers and sociologists.

The historian of the scientific study of society must accept all this accomplished work as the foundation of his own. He has, however, something fresh to contribute, and that something is of extraordinary value. One aspect of it is the attempt to relate the historical outlook and methods of each epoch and its theories of society to the political and social structure and the culture of that epoch. The other aspect is the attempt to assist the re-shaping of historical studies to harmonize with the political and social structure and culture of the present and the immediate future. In Great Britain the latter task is already in hand; for historical studies in recent years have been notable for their reflection of current interest in social and economic problems; to-day the weight assigned to social, economic and cultural history is perhaps as great as that given to political history. Research in the history of the study of society would demonstrate insistently the relativity of historical study and the need for its continuous readjustment to social needs.

In its narrower sense the history of the scientific study of society would have in view only the period, once the spirit and outlook of science, and in particular the application of these to the study of human society, have gained recognition. Here again, a distinction must be made between a wider and a narrower field. The historical research now in question could be extended to cover all the social sciences, or it could be restricted to sociology in its more limited sense.

This distinction corresponds to an ambiguity in the definition of sociology long recognized and discussed by sociologists[2]. Among these it is generally agreed that sociology deals with such matters as social organization, social development and the relation of the individual to society, attempting always to sort out the more general tendencies observable in particular societies and in human society as a whole. Some sociologists, however, have put forward much larger claims. According to these, sociology is and should be recognized as a general theory of human society in somewhat the same sense as biology is a general theory of living matter; each of the special social sciences would thus fall into place as a department of sociological study. So far, however, this view of sociology has failed to establish itself, one main reason being that the methods used by the various social sciences have been distinct and in some cases difficult to reconcile. Many sociologists would, however, agree that the narrower and wider views of sociology are not antagonistic, that the narrower view may be appropriate as defining a useful field of operations for the present, and that the wider view should not be dropped altogether out of sight.

Leaning now towards the narrower view, the need for research into the history of sociology as a recognized department of study may at once be admitted. Descriptive histories already exist[3], but it would be possible to plan useful researches that would examine the development of sociology in a more fundamental way than has as yet been generally achieved. Such researches would deal not only with the chronological development of sociological studies, but with the conditions that influenced and directed that development in each country at each period. They might also deal with the circumstances of the life of each individual sociologist who has made a material contribution to that development, and the influences that helped to shape that contribution. They might further attempt to answer the question: What function was sociology as developed at a particular time and place expected to fulfil and did it actually fulfil—in other words, How did it fit into the general structure of society and of ideas? They might also shed light upon the ways in which sociology has been influenced by and has influenced thought and ideas in other fields. If such researches extended sufficiently far they would in time provide a sociological account of the development of sociology.

The value of such researches is not affected by the question that must arise when definite projects are discussed: Can such inquiries be usefully separated (except for temporary practical convenience in handling) from the general study of the history of thought and the history of science which has developed rapidly in recent years? It is clear that they cannot; indeed, the attempt to isolate the history of sociology would itself be unsociological, as it would put in the background or out of sight the environment of thought in which the central body of sociological ideas has developed and to which it has always been intimately related.

The project may be further defined. It has been said that, in place of a single sociology, there are to-day many sociologies, each an outgrowth of some national or sectional tradition; for example, American sociology, Catholic sociology, Marxian sociology. Researches might be planned which would exhibit the development of each of these sociologies in its relation to the tradition and social situation of the nation or section from which it emanated. (These might incidentally serve to reveal the elements that are common to those various sociologies however much they may differ in their selection and treatment of material and in their conclusions.) Such researches could not well be separated except temporarily from much wider studies. Catholic sociology is a part of Catholic thought; the Marxian view of society is an essential part of the Marxian system; American sociology is inseparable from the modern American social constitution and outlook. A body of researches into the various traditions in sociology would inevitably bring under review those larger fields.

If the wider view is taken and the need of historical research on the development of the whole body of the social sciences is considered, no fresh point arises. In the case of each social science we need more exact knowledge of its relation to the conditions under which it was born and grew. The influence of each upon the others is also a fruitful field of inquiry. It is probable that such historical research might bring more clearly into view and define more exactly the differences in outlook and method that now separate the various social sciences so much more widely than is required by practical convenience. It is possible that the fuller understanding thus developed might help towards the co-operation and co-ordination of these sciences. It would, however, be inappropriate to pursue the topic here.

There is one further subject upon which research into the history of social science should throw some light. My old teacher, Victor Branford, used to say: "The difficulty about the acceptance of sociology in a particular society (*e.g.*, English society) does not lie in its ideas, which are simple, but in the lives of those who cannot accept it." By this he did not intend to suggest the possibility of some facile and universal use of sociology as a guide in the common affairs of life; he meant that the attitude proper to the sociologist—open-mindedness, endeavour to discover root causes, sympathy with persons of different age, culture and education—was extremely rare; or, more generally, that what he would have called a scientific attitude in and to social life had gained little recognition and acceptance. The fact will scarcely be disputed by those who have given serious thought to the subject. It has an important bearing on the development of sociology in the future, and it might be made the subject of a plan for intensive historical and contemporary research, to form part of an inquiry into the general attitude to scientific method and scientific results which now limits all scientific development.

REVIEWS

DECLINE AND REVIVAL OF ACID-BASE CATALYSIS THEORY

Acid-Base Catalysis

By R. P. Bell. Pp. viii+212. (Oxford: Clarendon Press; London: Oxford University Press, 1941.) 12*s.* 6*d.* net.

THE establishment of a new truth invariably evokes a number of new fallacies; the brighter the light that a new theory sheds on its proper field, the darker, and the more distorting, the shadows in which it submerges the experience which lies around the borders of its true scope. The striking success of the theory of electrolytic dissociation based on mass action law blinded scientific workers for more than twenty years to the necessity of invoking a new principle for the explanation of the marked deviations from this law in solutions of neutral salts and strong acids and bases.

An equally paralysing orthodoxy, which also had its origin in the earliest classical period of physical chemistry, was the strict separation between the problems of chemical equilibria and chemical reaction rates. It was the pride of the physical chemist to be immune against the tendency of the ordinary chemist to confuse the two fields, and he felt it to be his mission to emphasize on all occasions that the problems of chemical reactivity could not be dealt with by reference to thermodynamics. This prejudiced his mind against taking proper notice of parallels between reactivity and equilibrium constants, where such parallels did exist.

The inquiry on which Dr. Bell reports in his book has gone on continuously for the last fifty years and is still concerned with the questions which were foremost in the minds of van t'Hoff, Arrhenius and Ostwald at the birth of physical chemistry. Nor are the new solutions to these problems due to any considerable extent to the incursion of more recent ideas from other fields; the modern theory of strong electrolytes, the recognition of the primary and secondary salt effects, the generalization of the concepts of acids and bases and the discovery of Brönsted's law do not borrow important elements from outside the original domain of van t'Hoff and Arrhenius. These successes were rather due to the efforts of that unusual type of originality, which—resisting the temptation of glittering modern openings—continues to cultivate a shadowy field, considered by others as exhausted and ossified, and finally breaks the ban of orthodoxy and revives the fire of the original problems by insisting on fresh intuitions gained from a new contact with the experimental material.

Such was the quality of the minds which renewed the study of electrolytes and of acid and base catalysis during the past three decades. Among these, preeminent was J. N. Brönsted, to whom Dr. Bell pays a personal tribute in the introduction of his book, and to whose work much of the material collected in it is due. Another considerable part of this material is supplied by the author's own research work, through the pursuit of which he has gained that remarkable insight which guides his treatise through all aspects of the subject. These aspects are varied and can often be properly assessed only by a careful analysis of the chemical system and the prevailing experimental conditions, viewed in relation to a many-sided theoretical framework. A fair amount of such detailed discussion lends the book more the character of a critical report than that of a textbook. However, this makes it only the more useful to the advanced student, for whose use it is intended.

In the last few years before the War a number of attempts were made—in which Dr. Bell took an active part—to explain Brönsted's relation in terms of the atomic forces at play in the course of proton transfer. Dr. Bell's evaluation of these efforts will be most helpful to future investigators in this field. He points out the present gaps in the theory which look almost fatal, and yet asserts, and explains why, "it is difficult to believe that [it] does not contain the elements of the true explanation". He recognizes the limitations of the transition state theory, in particular where the activation energy of the reaction varies with temperature, yet makes good use of it for elucidating the general relationship between reaction rates and corresponding chemical equilibria. A chapter on "non-mechanical" proton transitions (tunnel effect) adds another field where a loosely fitting theory requires and seeks more substantial evidence. The open questions are again candidly discussed, yet the essential value of this line of investigation is effectively vindicated.

I was somewhat astonished to find no reference to such matters as G. N. Lewis's conception of proton-free acids; or Frumkin's connexion between Tafel's equation for the over-voltage of hydrogen and the laws of acid-base catalysis. But perhaps such omissions are required by the rigorously concise plan of the book, which reflects so truly the internal harmony of the curiously self-sufficient province which forms its subject.

M. POLANYI.

HISTORICAL GEOGRAPHY—THEN AND NOW

Geography and World Power

By James Fairgrieve. Eighth and revised edition. Pp. viii+376. (Bickley, Kent: University of London Press, Ltd., 1941.) 7*s.* 6*d.* net.

DURING the present century the subject of historical geography has developed from rather crude efforts to show how geography has influenced the course of history to the study of the use of possibilities by man in successive ages. Mr. Fairgrieve's book belongs to the earlier period, although its author has attempted to avoid obviously determinist doctrines by his definition of the word 'control'. "When we say", he writes, "that 'history is controlled by geography' we do not say that man is compelled by geography to use more and more energy, but that the precise way in which he has come to do this is largely controlled by his environment."

When one passes from the introduction to the main body of the book one realizes that the author has not wholly escaped from the contradictions inherent in the determinist view. The sea is "one of the great features whose power of protection has affected the world" (p. 21). But later (p. 329) examples are given of eleven powers which "have had sea power or ocean power depending, some almost entirely, others to a less extent, on the ease, cheapness and certainty of water carriage, and on a certain knack of the sea, bred of familiarity and use". It is strange to reflect that in 1941 the lesson has not been learnt that it is the British Navy, and not the sea, which has provided the "power of protection" to Great Britain and many another land. The disadvantage of Mr. Fairgrieve's interpretation of geographical control may be seen in his attempts to keep pace with the activities of man. In 1920, so great had been the material efficiency of Germany that "almost the united strength of the whole world" was required to overcome it. Yet "though the conflict ended as it did, that does not alter the geographical position of Germany nor the characteristics of her people". (2nd Edition, p. 224). Surely, then, one would have expected a warning that the War of 1914–18 would be repeated as soon as that "material efficiency" was again strong ? But Mr. Fairgrieve is no prophet : he remarks, in the present edition, that "material efficiency . . . has been the cause of war, and we should be rash to conclude that a final fixed state has been reached, for there has been no alteration either in the geographical position of Germany nor [*sic*] the characteristics of her people". Is this a real warning to us of the inevitability of events ? If so, it ought to be pressed with greater vigour.

Any writer who attempts to deal with world history and world geography in all ages in less than four hundred octavo pages invites criticism even if he does not deserve it. It is possible to quote many misstatements, or at least to express doubts on many of the positive assertions that are made. Thus the statement made in 1920, and repeated verbatim in 1941, that the sea-powers of France, Italy, and Portugal are "in league with Britain" scarcely expresses the facts. Magellan never "sailed round Cape Horn" nor did Napoleon "keep all his troops in the north" of Spain in the Peninsular War. One cannot readily accept the implications of many of the sketch maps nor appreciate the value of arrows liberally supplied on many of them. Yet the fact that this is an eighth edition of Mr. Fairgrieve's book must be taken both as a measure of the popular appeal of the subject and as a tribute to the author, whose pioneer work in geography should never be under-estimated.

J. N. L. Baker.

ROMANTICISM AND SCIENCE

Natural Science in German Romanticism

By Alexander Gode-von Aesch. Pp. xiii + 302. (New York : Columbia University Press ; London : Oxford University Press, 1941.) 20*s*. net.

HISTORIES of German literature usually distinguish a Romantic School of writers whose activities began in the closing years of the eighteenth century and continued until the fourth decade of the nineteenth century. The more obvious characteristics of these authors consisted of a certain antagonism to classical antiquity and to rationalism. They preferred the medieval and the mystical. They glorified the German past, and they fostered German nationalism and State-idolatry, the bitter fruits of which the world is now tasting, and not for the first time. More or less intimately associated with the Romantic School were certain famous philosophers—the brothers Schlegel, Schelling, Schleiermacher, and the arch-totalitarian Fichte. In the circumstances it was to be expected that German Romanticism would not be lacking in world-views of some sort. To find any unity or harmony in these world-views would be rather difficult in any event ; and Mr. Gode-von Aesch has increased his difficulties by including in the German Romantic movement some writers, like Goethe, Herder and others, who are not usually regarded as belonging to it. Sometimes, indeed, he seems to wander away altogether from the historic Romantic School, and to discourse about a Romantic world of thought without specific reference to individual representatives. At times, in fact, the reader gets the impression that the author has put together in his volume a number of separate essays which are not sufficiently interconnected to constitute a systematic exposition of the theme designated in the title of his book.

The speculative ideas embraced by the various representatives of the German Romantic School showed no originality. They were all taken over from ancient philosophy or medieval theology. Pantheism or panpsychism, the conception of man as a small world (microcosm) or of the world as a kind of colossal man (macroanthropos), the idea that love is what holds the universe together, and so on—these are all old thoughts ; and they are not made either better or worse by being put into verse. This does not necessarily detract from the merits of the German Romanticists. It is no mean achievement on the part of literary men to give effective expression to world-views, even if they do not originate them. In the volume under review the philosophical speculations of many more or less Romantic authors are described, illustrated and analysed with some critical acumen ; and all those who are interested in the study of German Romanticism will find much helpful material in this book. If its title had been "Philosophy in German Romanticism", its contents would have been described accurately, and no reader could have complained with justice that he had been led to expect something different.

The prominence given to "Natural Science" in the title of the volume is unfortunate. Of science, as the term is commonly used in English-speaking countries (that is, knowledge based on verification by experience), there is next to nothing in the thought of German Romanticism. Scientific terms like magnetism, gravitation, etc., it is true, occur with considerable frequency ; but they are usually associated with non-scientific speculations, not to say extravagant fancies. Thus, for example, we are told that "animal magnetism proves beyond a doubt that we have . . . a soul which consists of the divine spark". Again, the attraction and repulsion of material bodies are identified with love and hate ; and Empedocles is consequently proclaimed to have anticipated Newton. But it is unnecessary to multiply such examples, since it is admitted that "German Romanticism excelled in taking seriously all sorts of absurd quackery". In a sense, of course, there is plenty of romance in the history of science ; but romancing is not science ; and it is rather misleading to refer to such romancing as "Natural Science". In this connexion it may interest the author to be informed that, contrary to his assertion, Newton did *not* refuse to theorize about the causes of gravity ; what he did refuse was to regard such unverifiable speculations, including his own speculations, as a part of science.

A. Wolf.

NEWS and VIEWS

H.R.H. The Duke of Connaught, K.G., F.R.S.

By the death, on January 16, at the age of ninety-one, of the Duke of Connaught, the Royal Society has lost its senior Royal fellow, for he was elected so long ago as 1906 under the rule which permits of the election of "Any one of His Majesty's subjects who is a Prince of the Blood Royal". Apart from this distinction, the Duke was probably best known to scientific men as the president for many years past of the Royal Society of Arts, in the activities of which he took a keen interest. He was also president of the Royal Colonial Institute, a fitting acknowledgment of his statesman-like services as governor-general of Canada and on other missions to various parts of the Empire. His work as a public servant will go down in history as an important link in the chain which binds together the peoples of the British Commonwealth of Nations.

Letter from Sir William Hooker

Prof. J. Walton, regius professor of botany in the University of Glasgow, has recently acquired a letter (the text of which follows) written by Sir William Hooker, the well-known British botanist who was regius professor of botany at Glasgow during 1820–41, after which he was appointed director of the Royal Botanic Gardens, where he was followed by his equally illustrious son, Sir Joseph Hooker. The letter was written from Halesworth to Mr. Morris Pollock of Glasgow, on September 22, 1820. Prof. Walton informs us that it will be preserved in the University of Glasgow; he does not know whether the silver vasculum referred to still exists. The corrections and mis-spellings are as in the original manuscript.

"Let me beg of you to accepet for yourself & to offer to the rest of my friends, the students of my first years Claſs my sincere & grateful acknoledgements for the very beautiful Silver vasculum & the kind expreſsions of regard for me & my family contained in the addreſs therein inclosed, which have reached me this morning.

"The truly elegant box with its appropriate ornaments is greatly inhanced in value in my estimation (though this I feel to be intrinsecally far beyond what I can deserve) by the handsome manner in which it has been presented to me, & by a recolection of the smalneſs of the Claſs from whom I received it. Be assured that though I needed no token of your regard to urge me to exertion in the duties of my profeſsion in the University of Glasgow, I nevertheleſs have felt a gratification in receiving it which I know not how to expreſs, & which will render my return amongst those who have taken such an opportunity of showing their friendship for me & interest in my welfare doubly agreeable to me.

"I am still labouring in the cause of Scottish botany in the preperation of a Flora of your country which will be published before the commencement of my next years course. The occupation continually brings to my recollection plants that I have long ago gathered amidst the most delightful scenery, & which I little thought would have been turned to any account.

"Once more let me return you my sincere thanks for the most gratifying gift I ever received in my life, & through you let me offer to my other students the expreſsions of my acknowledgements & the affectionate attachment with which I have the honor to be, My Dear Sir your & their most oblidged & faithful friend & servant Wm. J. Hooker"

Regional Propositions for Tyneside

The second edition of Mr. D. M. Goodfellow's "Tyneside: the Social Facts" (Newcastle-upon-Tyne: Co-operative Printing Society, Ltd., 1941. 1*s*.) includes two further chapters on "Regions and their Planning" and on "Regions: the First Facts", which are relevant to the discussion of the regional propositions in the recommendations of the Royal Commission on Local Government in the Tyneside Areas, adoption of which in the main was recommended in the original edition of the pamphlet. The first of these new chapters reviewing the operation of the Town and Country Planning Acts in practice, suggests that the real difficulties in Tyneside are not due to problems of compensation but to the multiplicity of authorities. Territorial planning is a means for reviving and developing the manufacturing and agricultural industries of the area, but these positive purposes will never be realized with the present authorities, and in the second new chapter an area comprising the geographical counties of Durham, Northumberland and the North Riding of Yorkshire is proposed as a possible unit which might come to be defined as a local government region. Such an amalgamation would be a very different matter from one based upon the Mersey, Manchester or Birmingham, but amalgamations are probably most difficult where they are most urgent. However desirable the formation of regions may be, it would not of itself automatically solve all the problems.

A New Form of Government

In his pamphlet "A Sling against the Philistines: the New Machinery of Government by the People" Denis Becker (London: Andrew Dakers, Ltd., 1941. 9*d*. net) proposes the establishment of a Ministry and Court of Enlightenment as a means of freeing Parliament and Ministers from the influence of financial and other interests which stultify representation in Parliament and threaten the freedom of the Press. The Court of Enlightenment would consist of nominees of each of the principal universities, of the learned associations such as the Royal Society, the Law Society, the British Medical Association, the Headmasters' Conference; of each of the established royal societies devoted to the arts, such as the Royal Academy of Music, the Royal Society of Arts, the Royal Institute of British Architects; of each of the recognized ecclesiastical bodies; of the agricultural associations, of the Trades Union Congress and of the Employers Federation, with two or three nominees by the House of Commons and the House of Lords of outstanding members, two nominees by the Prime Minister of eminent men not connected with the institutions already specified, and a nominee of His Majesty's judges who would be *ex officio* chairman.

The nominees would be freely elected by the members of the institutions concerned at intervals not exceeding three years, and the Court so constituted would be charged primarily with the duty of advising the Prime Minister on the promotion of welfare and culture with special reference to the best use of the rising standard of knowledge, technique and scientific discovery. It would be responsible for the control of the B.B.C. and of the Ministry of

Education, and, through it, with the provision of the best form of education for the new generation, and also for the publication of a State newspaper. Mr. Becker further proposes that all Parliamentary debates should be broadcast in full on a separate wave-length, and he proposes new parliamentary methods. He claims that his proposals harmonize the three estates of sovereign power, represented by the people, executive power and the power of the mind; but he emphasizes also the need for a spiritual basis if any new machinery is to work successfully.

Inter-American Relations

THE U.S. Office of Education is publishing a new series of some twenty pamphlets under the general title, "Education and National Defence", with the purpose of assisting educational institutions and organizations to make the greatest possible contribution towards the promotion of understanding and the encouragement of effective citizenship. Pamphlet No. 13 in this series, "Hemisphere Solidarity", is a teacher's guide on inter-American relations with special reference to Latin America, designed for senior high schools, to assist a better understanding of Latin-American neighbours and their contribution to the welfare of the western hemisphere as well as to stimulate thought on vital problems affecting mutual co-operation among the nations concerned. In addition to a discussion of methods of teaching hemisphere solidarity, it includes a suggested outline of problems and activities and a useful bibliography on sources of information.

Sir Charles Parsons and Turbo-driven Fans

THE Christmas issue of the *Heaton Works Journal*, which deals with the activities of Messrs. C. A. Parsons and Co., Ltd., contains an article on early turbo-driven fans. In 1894, when Sir Charles commenced his experiments on turbo-driven centrifugal pumps, he constructed the first turbo-driven fan. This was to the order of Ramage and Ferguson, Ltd., of Leith, who fitted it on board the S.Y. *Speedy* for supplying forced draught to the boilers. The unit was a very small one, the turbine developing about 3 h.p. at a speed of 4,000 r.p.m. The fan was of the screw propeller type, but no particulars of its duty or its dimensions are to be found among the records at Heaton Works. In the following year Sir Charles took out a patent, No. 3024, covering "Improvements in Stationary and Portable Pumps Actuated by Steam Turbines". The first part of this patent deals with turbo-driven centrifugal pumps, while the latter part is devoted to turbo-driven fans. The first of the figures given shows a modification of his invention in which he applies the turbine directly to a screw fan for forced draught, or ventilating purposes. One of the steam turbines is directly coupled to the fan shaft upon which the screw fan is fixed. It revolved at a speed of 2,000–3,000 revolutions per minute, gave a pressure of 12–22 in. of water and delivered 5,000–7,000 cu. ft. of air per minute. Simultaneously the second turbo-driven fan was constructed for the lead works of Messrs. Cookson and Sons at Howdon-on-Tyne. Like the first fan, it was required for forced draught purposes. The turbine developed 60 h.p. at 3,000 r.p.m. and operated with steam at 80 lb. pressure. The fan, which was 36 inches in diameter and directly coupled to the turbine shaft, delivered 60,000 cu. ft. of hot lead gases per minute at a pressure of 5 in. of water when running at 3,000 r.p.m. The plant was run for nearly seven years day and night (Sundays included) in hot lead fumes, at a temperature of nearly 500° F. and was only stopped twice a year, to allow of the flues being cleaned out.

Octonarian Weights and Measures

IN "Octonaria" (*Math. Gaz.*, October, 1941) "Peter Simple" gives, in an account of an imaginary State, what is really a plea for a system of numeration and weights and measures based upon eight instead of ten. It is urged that continued divisibility by two is a property of the greatest importance. For example, the seven weights, each double the last, of 1, 2, 4, 8 ounces, and 1, 2, 4 pounds will make up every weight, to the nearest ounce, up to 127 ounces, whereas with the seven metric weights 1, 2, 2, 5, 10, 10, 20 grams, we get only as far as 50 grams. Some of the existing British measures fit easily into the octonarian system. For example, 8 pints = 1 gallon, 8 gallons = 1 bushel, 8 bushels = 1 quarter. As for money, if the crown (one eighth of £2) were divided into sixty-four pennies instead of the present sixty, each new penny would be fifteen sixteenths of the old.

The further proposal to have an octonarian system of numeration is more startling. In this, 10 would denote eight, 20 twice eight, 100 eight times eight, and so on. It is obvious that the risk of confusion would be very great, and the author's suggestion that 20 should still be called twenty, although denoting twice eight, seems to be a gratuitous increase of this risk. The plea that this system would reduce the length of the multiplication table does not seem a sufficient recommendation. The duodecimal system, which has many advocates, as allowing division by three as well as by four, is rejected by the author on account of the extended multiplication table necessary. There is one possibility not mentioned in this paper. If the octonarians and duodecimalians press hard enough, the British spirit of compromise may split the difference between eight and twelve and adopt a decimal and metric system.

Luminous Paint

IN NATURE of November 1, p. 529, reference was made to luminous strontium sulphide and its possible use for A.R.P. purposes. Dr. S. Rothschild points out that although this substance has a long afterglow when fresh, owing to its great sensitivity to moisture it soon deteriorates, even when protected with a special coating. It is only stable when kept airtight between glass plates and to a certain extent when embedded in plastics. Luminous calcium sulphide is less sensitive to moisture but also less bright. Luminous zinc sulphide, however, is stable even in damp rooms and is now obtainable with an afterglow sufficient for A.R.P. purposes.

A similar luminous effect can be obtained by illuminating a fluorescent substance with the appropriate radiation. The B.A.B. fluorescent system of lighting (Colloidal Research Laboratories, Ltd., 66–70 Petty France, London, S.W.1) has been applied successfully to mark the approaches to Piccadilly Underground Station and elsewhere. The fluorescent substance is applied in the form of hard wearing lacquer on a white undercoat, and is illuminated by either a mercury vapour or a white light lamp fitted with a 'black glass' screen which is claimed to pass only the band 3340–4000 A., thus absorbing the dangerous radiations of shorter wave-length.

Health of Tanganyika

THE chief points of interest in the recently published annual report for 1939 of the Medical Department of Tanganyika Territory are the plans for the development of a native medical, nursing and public health service. The War has interfered with plans for nutritional investigations and relief for deficiencies, although a start has been made. As regards the incidence of various diseases the most important facts are as follows: the discovery of two fresh foci of sleeping sickness (663 cases with 184 deaths), cerebrospinal fever (2,183 cases with 237 deaths), the discovery of a plague-infected rat, and an investigation of smallpox. 248,533 cases of infectious and parasitic diseases were reported from various Government institutions. The most frequent diseases were as follows in the order named: yaws, malaria, syphilis, ankylostomiasis, gonorrhœa, schistosomiasis and tuberculosis. The population of Tanganyika in 1939 was: Europeans 9,165, Asiatics 33,974, and Africans 5,217,345.

The Completed Map of North East Land

ALTHOUGH North East Land, the most easterly island of the Spitsbergen group, was known to the seventeenth-century whalers, it was relatively unexplored until some twenty years ago, except for an attempt by A. E. Nordenskjöld in 1873. The modern survey, begun by the Oxford University Expedition of 1924, was virtually completed by the Oxford Expedition of 1935–36, though some important work was done by the Swedish-Norwegian Expedition of 1931. The map published in the *Geographical Journal* of October 1937 is now revised in some minor and one major point by a new map in the *Geographical Journal* of October 1941 (A. R. Glen, "The Latest Map of North East Land"). This map makes use of the Norwegian aerial surveys of North East Land in 1938 which are not now accessible, and it shows one remarkable change. In the south a great lobe of the South Ice has overridden the coast on a thirteen-mile front and pushed ten miles out to sea. Recent investigations show that the ice of North East Land is in the main in retreat: small ice-free areas have been found on the east coast. This advance is probably purely local, and Mr. Glen suggests that it may be due to a tectonic disturbance or some internal glacial cataclysm. The whole surface of the ice lobe is heavily crevassed.

National Central Library

THE twenty-fifth annual report of the executive committee of the National Central Library for the year 1940–41 refers again to the special war work of the Library for Government departments, research stations and industrial concerns, as well as to the service organized in co-operation with the county libraries and the Scottish Central Library for Students, for the supply of educational books to men serving in the Army in all parts of the British Isles. A similar service has been given to men serving in the Royal Air Force, and the Library has also been able to assist men serving in the Royal Navy and in the Mercantile Marine through the agency of the Seafarers' Education Service. At the request of the Home Office, the Library has organized, with the assistance of the local urban or county libraries concerned, a service for the supply of educational books to aliens in internment camps. The Library has acted as agent of the American Library Association's Committee on International Relations in connexion with the distribution of American books and periodicals to men serving in the British Forces at home and overseas. With the assistance of the British Council, the Library has also been instrumental in supplying books in their own language to sailors, soldiers, airmen and civilian refugees from Czechoslovakia, Greece, Holland, Poland and other Allied countries now in the British Isles.

When the Treasury grant in aid to the Library for the year 1940–41 was reduced from £4,800 to £3,500, the trustees of the Rockefeller Foundation made an emergency grant of 8,500 dollars for the year 1940–41, and the Foundation has continued to provide money for the upkeep of the Bureau of American Bibliography. The trustees of the Carnegie United Kingdom Trust continued their grant of £4,000. The total number of books issued during the year decreased from 50,611 to 39,420, issues to university libraries being 2,433 as against 3,046 in the previous year; of these, 1,100 were supplied by university libraries themselves.

Museum of the Royal College of Surgeons

THE scientific report of the Royal College of Surgeons for the year 1940–41 states that the Museum and store rooms were hit during an air raid, incendiaries increased the damage, falling girders broke up the basement below, and heavy rain the following days drenched the exposed specimens. The loss, though serious, was not complete. In the anatomical series 1,207 specimens survived out of 2,569. In the osteological series, out of 1,655 Hunterian specimens only 94 were saved, and 6,209 of 15,545 College specimens. On the other hand, the whole of the odontological series was saved. Nearly half the 5,400 Hunterian physiological specimens escaped, but only 2,026 of the 14,850 College specimens in this series. Of the human and comparative teratological specimens only 23 of 170 Hunterian specimens remain, but the College specimens have largely survived. The better part of the Hunterian pathological series remains, but the College specimens have been reduced to about a fifth, and the whole of the Townbee and Strangeways collection has gone; the Army Medical War Collection has been reduced from 3,000 to 100. All the mummified specimens and the historical collection are lost, and the instruments collection has been reduced from 2,500 to 2,000. The zoological and anthropological pictures have survived, including Tonks's war pictures. The total loss of specimens amounts to 39,259 out of 65,827.

Vacation Apprenticeship Scheme

THE value of practical training, and of a close linkage with industrial practice during the undergraduate years, is receiving more and more recognition in scientific academic circles to-day. This is the case, not only in the engineering faculties, but also in branches of pure and applied science—chemistry, physics, and even biology. That this is also appreciated and valued by industrial firms themselves is apparent from the steadily growing success that has attended the Vacation Apprenticeship Scheme carried on by the Imperial College Union for the benefit of students of all departments in the Imperial College of Science and Technology. From its inception seven years ago, the scheme has shown a steady record of progress in spite of the uncertainties of the past few years. In the summer of 1941, for example, 124 firms accommodated 181 students, granting them the opportunity to receive valuable experience in many of the experimental and production processes. The reports of the firms and of the students show how well and how smoothly the scheme is working. It is significant in this connexion that since the inception of the scheme, the average earnings per student reached its peak in 1941. During the summer vacation, July–September, 1942, more than three hundred students of the Imperial College will be available for varying periods of from six to eight weeks, and there is evidence that the co-operation of industry is likely to expand with this growing demand for absorption.

The Linnean Society of London

THE Linnean Society of London is now holding some of its meetings (those of zoological interest) in conjunction with the Zoological Society of London. The Society has decided to invite by name botanists and zoologists who are refugees in Great Britain to attend the general meetings of the Society. If, therefore, any such botanists or zoologists will make application to the Assistant Secretary, the Council will consider the issue of invitations to attend the meetings.

The following discussions are being arranged by the Society: (1) "The biogeographic division of the Indo-Australian Archipelago; criticism of the Wallace and Weber lines, and of any other dividing lines, with an attempt to obtain uniformity in the names used for the divisions". The subject will be introduced by an account of the geological history and climates of the Archipelago, by Mr. J. B. Scrivenor, lately director of the Geological Survey, Federated Malay States (in April); (2) "Time, temperature and humidity in the germination of seeds", to follow an address on "Recent work on germination", by Dr. M. A. H. Tincker (on May 14); (3) "Intertidal zonation of animals and plants", introduced by an address on "The causes of the zonation of animals and algæ between tide marks", by Prof. T. A. Stephenson (on June 18).

Broadcasts on the Sub-visible Universe

A SERIES of twelve talks under the title "Science Lifts the Veil", which deals with the structure of matter, is being given on Mondays in the Empire programme of the British Broadcasting Corporation. The talks, which were introduced by Sir William Bragg on January 5, have been arranged with the advice and assistance of the Science Committee of the British Council. Sir William Bragg explained the idea and significance of the theme. He pointed out that the growth of science and of its power is largely due to an increasing ability to see or recognize smaller and still smaller things. The range of the unaided eye is limited, and it has been natural to ignore what cannot be seen. The microscope opened the way to more thorough knowledge; other means have been developed in succession. As each fresh veil has been lifted from the regions of the sub-visible universe, a new range of knowledge has been revealed, and this has in many cases provided mankind with new powers over materials, life and health. The talks, which are being given by leading men of science, will explain the revelations that have come with the magnifying glass and the microscope, X-rays, the electron-microscope and other aids to he exploration of the small. Their effect on the many forms of science, on those which deal with natural processes, the living cell, bacteria, health and disease, on those which deal with human construction, dyes, drugs, alloys, textiles and the materials handled every day, on those sciences which are concerned with the production, preservation, and the use of food, will be explained by men who have themselves taken part in the conquest of this sub-visible universe.

Hill Sheep Farming

THE Agricultural Improvement Council for England and Wales has set up a Committee "to investigate the present position of hill and upland sheep farming in England and Wales and in the light of modern scientific knowledge to suggest measures that might be taken to improve the condition of hill and upland grazings, the health and hardiness of sheep stocks and systems of stocking and management". The Committee is constituted as follows: Lord De La Warr (chairman); Mr. J. C. F. Fryer, Mr. Moses Griffith, grassland adviser at the Plant-breeding Station, Aberystwyth; Mr. David Lewis; Dr. R. F. Montgomerie; Prof. G. W. Robinson, professor of agricultural chemistry in the University College of North Wales, Bangor; Dr. R. W. Wheldon, lecturer in agriculture at King's College, Newcastle-upon-Tyne; Mr. W. Wilson. Mr. D. H. Dinsdale, adviser in agricultural economics, King's College, Newcastle-on-Tyne, will act as technical secretary to the Committee, and the administrative secretary will be Mr. J. H. Banbury, of the Ministry of Agriculture and Fisheries, Lindum Hotel, St. Annes-on-Sea, Lancs.

Announcements

SIR JOHN RUSSELL, director of the Rothamsted Experimental Station, has been appointed adviser to the Soviet Relations Branch of the Ministry of Information. During his well-known researches in agricultural science, Sir John has come into close contact with Soviet men of science and has travelled widely in the U.S.S.R.

MR. J. K. ROSS has been appointed assistant conservator of forests, Sierra Leone, in the Colonial Service.

PROF. ERWIN PAYR, emeritus professor of surgery at Leipzig University, has been awarded the Goethe Medal for art and science.

To meet urgent needs, some of them arising from the War, four new teaching departments have been set up at Leeds General Infirmary, devoted respectively to thoracic surgery, physiotherapy, radiography and radiotherapy, and dietetics.

THE Board of Education announces that the scheme of State bursaries in science, tenable at universities and certain technical colleges, carrying fees and maintenance allowances, which was instituted last year to meet the demand for technical officers for the Armed Forces and for war industry, is being continued in 1942. Bursaries will be awarded as last year in engineering, physics-with-radio, and chemistry. Full particulars are being sent to the headmasters and headmistresses of secondary and public schools.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Excitation of Nematocysts

THERE has in the past been considerable discussion concerning the nature of the stimulus which causes the nematocysts of Cœlenterates to discharge. In some cases, it is quite clear that the mechanical stimulus to the cnidoblast causes an explosion of the enclosed nematocyst. But for the majority of nematocysts, discharge only takes place in the presence of food, and it has been suggested that the stimulus is essentially a chemical one. During a long series of experiments on the feeding of *Anemonia sulcata*, interesting evidence has been obtained as to the mode of excitation of nematocysts. In agreement with Parker and Van Alstyne[1], I find the cnidoblasts of the tentacles of Anemonia are independent effectors. They respond, however, selectively to food. If touched by a clean glass rod, no discharge is normally obtained. If touched with a piece of human skin, there is copious discharge. The discharge, however, only takes place where there has been mechanical contact. Strong food solutions sometimes seem to cause spontaneous discharge of a few nematocysts. But it is easy to show that this is of no direct significance in the normal reaction. As a direct chemical stimulus, food is far less effective than certain surface-active substances such as bile salts (0·1 per cent), which produce a complete spontaneous discharge of the nematocysts. This action is, however, quite different from the normal response. Cotton wool soaked in dilute bile salts does not adhere to the tentacles ; the nematocysts being discharged by the diffusing bile salt before contact is made. On the other hand, cotton wool soaked in food solution causes extensive discharge of nematocysts into the mass on contact. This is true even though the food solution employed is far below the concentration for spontaneous discharge. Clean cotton wool, soaked in sea water as a control, produces no discharge.

A simple experiment helps to explain these curious facts. If a tentacle is touched by a small clean glass bead, no nematocyst discharge takes place. If the tentacle is now immersed in food solution, for example, 10 per cent human saliva in sea water (centrifuged), there is little or no evidence of spontaneous discharge. But if the tentacle is now touched with a clean glass bead, a profuse discharge of nematocysts takes place on to the bead. Clearly, the food solution has acted by lowering the threshold to mechanical stimulation. We have in the cnidoblast the remarkable system of an independent effector excitable by a mechanical stimulus, but only excitable in this way when under the influence of specific chemical substances in the food.

Analysis of active food material shows that the effect is not given by carbohydrates or carefully fat-freed proteins or their derivatives. The active substance is normally strongly adsorbed on protein, whence, however, it can be extracted by alcohol or acetone, though not by ether. The obvious suggestion is that the active substance is a lipoid possessing polar groups. This suggestion is borne out by the fact that glass beads coated with trimyristin produce a discharge on coming into contact with the cnidoblasts. The results of this work will be published in a forthcoming paper.

Dr. J. H. Schulman of the Department of Colloid Science, Cambridge, and I have investigated the effect of a number of surface-active substances, both with respect to spontaneous discharge and to the normal contact response. The effects are highly selective. Whereas the salts of bile acids produce nematocyst discharge at low concentrations, many other capillary-active compounds such as the sulphate, amine or carboxylic salts of long-chain aliphatic substances cause no obvious spontaneous discharge, even in concentrations sufficient to cause rapid cytolysis.

Of the substances tested, the contact response was greatest to aliphatic esters such as trimyristin and ethyl stearate. Even pure paraffin wax can produce a moderate contact discharge of the cnidæ. On the other hand, long-chain fatty acids in which the surface is hydrophilic, or paraffin rendered hydrophilic by the presence of fatty acids or protein is without effect. This strongly suggests that the lipoid substance concerned must come in actual contact with the lipoid surface layer of the cnidoblast in order to exert its effect. These results will be published in another paper.

Properties of Cuticle and Insect Ecology

THERE is no doubt that the physiological significance of insect coloration has not yet been fully realized by ecologists, while its direct survival value has often been overstressed. From this point of view Dr. Kalmus's article in NATURE[1] is to be welcomed. His treatment of the problem, however, is such that it may bring undeserved discredit to essentially sound ideas. Starting with references to some recent investigations on the physical properties of insect cuticle, Dr. Kalmus proceeds to formulate thirteen "Rules", based on the still scanty results of those investigations, on a number of assumptions (for example, "a dark cuticle is mechanically the stronger", which he admits to be an assumption not yet proved, but on which no less than four "Rules" are based), and on teleological speculation. The evidence quoted in support of each "Rule" is exceedingly meagre and often inaccurate, as a few examples will show. The mole cricket quoted in Rule 3 is not "entirely dark" but paler than most of its relatives. Rule 4 ("giant forms are usually black ; bright colours are more frequent among small insects") is not supported by any evidence, and its correctness is highly doubtful. Mayflies, on the sole support of which Rule 9 rests, are not necessarily pale and some are even black. Eggs of Phasmodea (Rule 10) are not "dark and hard", but always hard and only sometimes dark. Rule 11, stating that "most non-black insects are found in the tropics" has since been presented[2] in a more intelligible way by saying that "the proportion of non-black insects is greater in the tropics", but it is legitimate to ask on what evidence this statement, implying the existence of some numerical data, is based. Similar statements of alleged quantitative character constitute many of the "Rules", and it is surprising that they should emanate from a University Department of Biometry where more respect for statistical data would be expected.

The lack, or inadequacy, of evidence in support of the "Rules" caused me (in a letter to Dr. Kalmus) to call them dogmatic, and Dr. Kalmus is merely using a polemical trick in contrasting this definition[2] with that of Prof. Hale Carpenter[3], who criticizes them for being vague. The fact is that most of the "Rules" are dogmatic, though the wording of some of them is vague. This vagueness ("usually", "frequently") anticipates all criticism based on concrete examples; a further safeguard is provided by explaining that the effects of the thirteen "Rules" are often contradictory and final results difficult to foretell; still further, all cases of coloration dependent on subcuticular pigmentation are brushed aside as irrelevant, although, for example, the absorption of heat radiation by a black insect does not depend on the histological location of the black pigment. In fact, Dr. Kalmus's attitude seems to be this: dark (or light) colour of any insect species must have *some* teleological reason, and if the colour contradicts one "Rule", another can be applied, until an "explanation" of the colour is found. As there are thirteen "Rules", the choice is wide. The technique of applying the "Rules" has been excellently demonstrated by Dr. Kalmus himself, in reply to Prof. Hale Carpenter's[3] query as to why in Ngamiland the diurnal Tenebrionids and the nocturnal Carabids are both black. The answer is "I think the beetles of Ngamiland provide quite good examples of Rules 12 and 14 (drought and vagility)". What kind of ecologist would be satisfied with this light-hearted way of solving his problems? Another example of Dr. Kalmus's versatility concerns weevils, the integuments of which are usually very hard, whatever the colour (thus refusing to observe "Rule" 3); in this case "a different process of hardening seems to be at work".

It is really incomprehensible why Dr. Kalmus formulated his points as "Rules". If he had said, for example, that long-lived insects *may be expected to be* darker than their short-lived relatives, it would have been a reasonable deduction from properties of cuticle; but saying, as he does, that "long-lived insects *are* darker, etc." amounts to a dogmatic statement, which is possibly untrue. Most of the thirteen points deserve the attention of ecologists, since they suggest problems concerning physiological causes and biological effects of coloration; but it is to be sincerely hoped that no ecologist will be tempted to explain away his problems by consulting Dr. Kalmus's list of rules, or to follow his example of solving them with the aid of meagre physiological data, supplemented by wishful thinking on teleological lines.

In my article I proposed a system of deductions from newly discovered physical properties of cuticle, formulated them as ecological rules and illustrated them by some examples. As the working mechanism of adaptation I postulated natural selection, thus escaping, as I hoped, the accusation of teleology.

If, as Dr. Uvarov recommends, ecologists interest themselves in these deductions, their observations will show, in due course, how many of my ideas are sound.

H. Kalmus.

Difference in Resistance to Toxic Substances of Mutants of Drosophila of Different Body Colour

In previous papers[1,2] it has been shown that mutants of four species of Drosophila with light-coloured cuticles are less resistant to desiccation than are those of darker body colour. This was taken to indicate that the light cuticles are more permeable to water than the dark. The following differences in resistance of the light and dark insects to various toxic substances may also be explained by differences in the permeability of the cuticles.

Heavy and light petroleum oils, a tar-oil emulsion in water, a pyrethrum extract and weak solutions of sulphuric acid were sprayed on batches of flies taken from a segregating F_2 generation by means of an apparatus[3] designed to give uniform replicable deposits of known amounts of contact insecticides. The flies were supported on a textile material (tricoline) and males and females of the mutant and wild type flies were treated at a time, the insects being previously narcotized with carbon dioxide.

The *yellow* mutant of *D. pseudo-obscura*, race *A* and *D. melanogaster* showed a significantly lower resistance to all the substances tested as measured by the number of survivors, when compared with the wild type. The mutant *black* in *D. melanogaster* showed a slight increase in survival, whereas there appeared no difference between the mutant *ebony* in the same species and the wild type.

The yellow mutant of *D. pseudo-obscura* lost more weight after spraying with heavy or light oil than the wild type. The loss in weight of both forms was greater after treatment with the more volatile oil.

A collapse of the eyes of the dead flies was noticed after treatment with the light oil. The frequency of this effect was significantly greater in the yellow mutant of *D. pseudo-obscura* than in the wild type. This effect was not observed with the other substances.

It is not clear at present whether the differences in reaction of the mutants to all the chemicals used are due to a common cause. With the exception of pyrethrum, the substances tested or related products are likely to be found in the atmosphere, precipitations and on the vegetation of industrial districts. The differential behaviour between the light and dark insects found in these experiments may thus provide an explanation for the progressive selection of melanic forms in these areas.

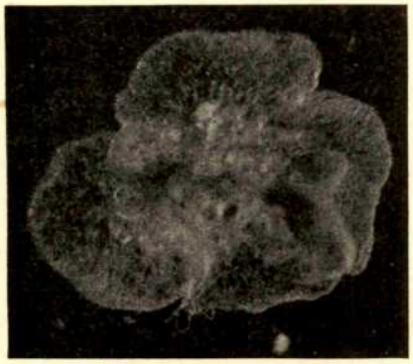
A Ctenophore from the Palestinian Coast

Some six weeks ago I set up a series of small sea-water tanks. One of these was planted with *Caulerpa prolifera*, *Caulerpa crassifolia* and Zostera sp. On October 29 we noticed in this tank three specimens of a creeping Ctenophore.

All the material present was from the Palestinian coast, near Jaffa. So far as known to us, no Platyctenean has up to now been described from the Mediterranean. Therefore we presume that we are dealing with the Red Sea form (*Cœloplana Metschnikowii* Kowalewsky, 1880) or else with a new species. If our specimens should belong to the Red Sea species, this would mean that this interesting animal—like many others—has succeeded in penetrating through the Suez Canal into the eastern Mediterranean.



A preliminary examination tends to confirm this diagnosis of the genus Cœloplana: the animal appears to be devoid of comb-plates but possesses the characteristic aboral papillæ of Cœloplana. The animals are 12–13 mm. long and 9 mm. broad, and they were observed both creeping on the substrate and hanging on the water surface. One specimen swallowed an Isopod of 2 mm. length. The tentacles can be extended more than 15 cm. The accompanying photograph, taken by Dr. W. Koch, shows a specimen with one tentacle partly extended.

Northern Fringe of the Palæolithic in England

The question as to whether the northern fringe of the Palæolithic in England extended into Yorkshire or not has long been a matter of controversy. Certain archæologists have supported such an extension on the ground that many palæolithic types of implement have been discovered there, while most geologists have denied it on the ground that climatic conditions would have rendered any human penetration of Yorkshire impossible throughout the Ice Age.

For a thesis recently accepted by the University of Durham I have made a close investigation of this problem, re-examining both the implements discovered and the details of their discovery.

The investigation has revealed that many of the implements are undoubted palæoliths, but do not belong to any of the earlier Palæolithic cultures, being, with the possible exception of one group from Nidderdale, Debased Creswellian. At two sites at least, one in the Huddersfield region and the other near Settle, these palæoliths were certainly deposited prior to the earliest appearance of Mesolithic influences. The strata in which these palæoliths occur, in all cases where they can be identified, are post-glacial in date. The Palæolithic sites, almost without exception, are situated on elevated ground, the majority on the Pennine Ridge, a few on the Yorkshire Moors and Yorkshire Wolds. The genuine palæoliths are few in number compared with the implements of later cultures; a few of the stone implements are of flint and comparatively well made, but the majority are of chert and exceedingly crude. As a general rule the better-made implements are the earlier, the more crude the later, though the latter tend to improve slightly as the period draws to a close.

These facts make it clear that there was a Palæolithic period in Yorkshire, but that this period was post-glacial, not interglacial, in date. Thus the opposed views of the geologists and the archæologists can be largely reconciled.

It is possible to reconstruct in broad outline the sequence of events which brought about the above-mentioned conditions. The Creswellian Culture is known to have persisted in Derbyshire and Lincolnshire long after the contemporary palæolithic cultures on the Continent and even in southern England had been superseded by the Mesolithic[1]. During this period the ice withdrew from the greater part of Yorkshire, and immediately small hunting parties began to enter that county, keeping to the elevated ground, as the valleys and plains would still be impassable.

At first these parties would be mere seasonal visitors, returning to the Derbyshire and Lincolnshire centres for the winter; but as conditions improved, some at least settled in Yorkshire, living the life of nomadic hunters. The original migrants would take with them flint tools and weapons manufactured by skilled workmen at the North Midland sites, thus accounting for the comparatively well-made implements; but their descendants would have to improvise with the somewhat intractable local chert, which explains the deterioration of the workmanship.

There appears to have been a break in these migrations, during which mesolithic influences reached the Derbyshire and Lincolnshire sites, and when conditions further improved and a general advance northward was made, it was by a people in a mesolithic stage. The descendants of the earlier migrants were then either absorbed or became extinct.

It is hoped at some future date to publish full details of the evidence on which these conclusions are based, as well as a discussion of several subsidiary questions arising out of the main problem.

Names of Electrical Units

If the E.S.U. system is to be retained, Dr. E. A. Guggenheim's suggestion[1] that the unit of electrical charge in this system should be called the "franklin" has much to commend it. But why retain the E.S.U. system? The object of the M.K.S. system is to replace three existing ones, with their cumbersome conversion factors, by one single system which meets all practical requirements.

It is unsound to give an arbitrary unit value to more physical quantities than necessary, though the practice is sometimes unavoidable (we can, for example, scarcely hope to avoid using the horse-power as well as the watt), but in electrical work there is no need to give an arbitrary value to more than one quantity in addition to the three mechanical ones of length, mass and time. In the M.K.S. system the quantity selected for permeability is 10^7 that of a vacuum. This automatically causes the permittivity of a vacuum to be $1{\cdot}113 \times 10^{-10}$ units. Arbitrarily to make the permittivity of a vacuum one unit as is done in the E.S.U. system is to over-determine the units. It is very much to be hoped that this practice will be dropped, particularly as the exact conversion factor is not such a round figure as given in Dr. Guggenheim's table. It would only be so if the velocity of light were exactly 300,000 km. per second, which it is not.

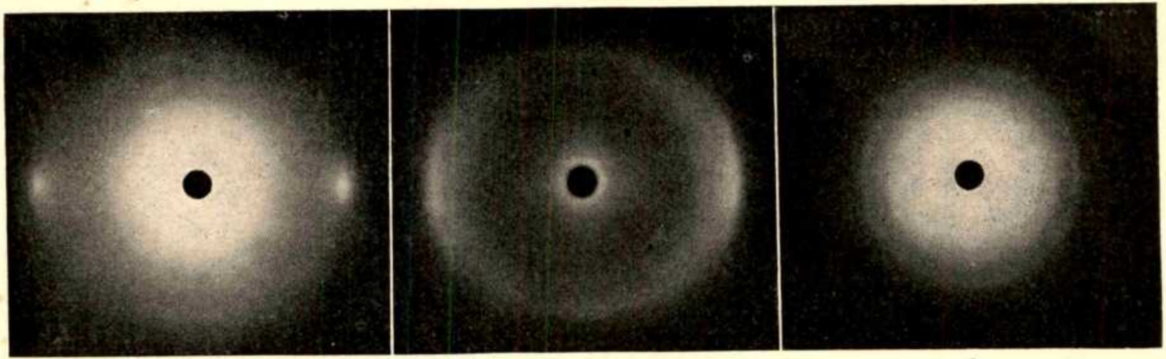
Crystallization in an Inflated Rubber Balloon

IT is well known that an oriented crystallization is produced in rubber by stretching. The rubber can be made to crystallize also by a two-dimensional homogeneous dilatation, as in the skin of an inflated rubber balloon. I have experimented with small balloons of about 1 cm. diameter when slack, made of pure vulcanized latex by dipping. When a balloon like this is inflated to 3–4 cm. diameter and an X-ray beam strikes the sphere tangentially, photographs result as shown in Figs. 1 and 2, taken with balloons approximately 0·1 and 0·6 mm. thick when slack. The spacings given by the reflexions in the horizontal plane, which contains the centre of the sphere, is 4·22 A.; those of the short arcs at top and bottom are 4·95 A. and 6·24 A., corresponding to the (200), (012) and (002) reflexions in the ordinary fibre diagram which was taken separately. The arcs are blurred as they originate on an extended area of the sphere. The sharpness of the horizontal reflexions, on the other hand, is enhanced by a focusing effect.



1
Thickness, 0·1 mm., inflated to 31 mm. diameter. Distance, 8 cm., beam tangential.

2
Thickness 0·6 mm., inflated to 49 mm. diameter. Distance 8 cm., beam tangential.

3
Same as 2. Distance 6·5 cm., beam through centre.

X-RAY DIAGRAMS, TAKEN WITH UNFILTERED COPPER RADIATION, OF INFLATED RUBBER BALLOONS.

Accepting a monoclinic structure with an angle $\beta = 83° 20'$ as proposed by Lotmar and Meyer[1], the dimensions of the elementary cell work out as $a = 8{\cdot}5$ A., $b = 8{\cdot}2$ A. and $c = 12{\cdot}6$ A. for this particular specimen; b is the fibre axis indicating the direction of the main valency chain.

With this assumption, we interpret the result represented by Figs. 1 and 2 as follows. The dilatation of the rubber skin produces an oriented crystallization, the orientation being brought about by a tendency of the crystallites to arrange themselves with the b-c-plane in the plane of the skin, that is, with the shorter a-axis perpendicular to the skin. The distribution in the plane around the normal is at random, giving as reflexions parts of Debye rings.

The effect is less marked in the thicker specimen, as will be seen when comparing Figs. 1 and 2. Fig. 3 is a photograph taken with the X-ray beam passing through the centre of the sphere. This gives, of course, two sets of reflexions, from the near and the far side of the balloon respectively. The second one is scarcely visible in the reproduction. There are two Debye rings each with spacings equal to the (002) and (012) reflexions of which the latter is much stronger. The (200) reflexion is either completely absent or extremely weak. These findings appear to corroborate the proposition outlined above, which indeed is closely connected with what is known as 'higher orientation' in thin stretched rubber bands.

A Reversible Discharge Tube

IN a recent letter, Asundi, Singh and Singh[1] have described effects observed with a so-called reversible discharge tube. The phenomena recorded appear to be most easily explained by assuming that the discharge tube leaked slightly. This would account for the appearance of the hydrogen spectrum when the tube was freshly swept out with hydrogen, the appearance of nitrogen bands after standing, and the reappearance of the hydrogen spectrum on continuous running, the nitrogen being cleaned up by the aluminium electrodes, a well-known effect which is commonly made use of in hydrogen discharge tubes. The cleaning up would not occur so readily with external electrodes, and hence the discharge tube would be expected to continue to show nitrogen bands.

RESEARCH ITEMS

The Veddahs of Ceylon

An important addition to our knowledge of the Veddahs of Ceylon has been made by W. C. Osman Hill, professor of anatomy, Medical College, Colombo (*Ceylon J. Sci.*, Sect. G, Anthropology, 3, 27; 1941). He has taken an extensive series of measurements of 34 living males of the race, noting in particular colour and hair development; 16 members of the series measured came from one group or clan—the Danigala. He adds measurements and descriptions of 68 skulls and 28 skeletons—most of which are in European museums, but others have been obtained from original sources. Particularly valuable are the photographs of living natives, among which one recognizes not only the more common Veddah type but also others showing resemblances to the Australian aborigine and to negroid peoples. These aberrant types also appear among the Dravidian-speaking tribes of Southern India. Dr. Osman Hill finds the outstanding characteristics of Veddahs—as of all dwarf races—to be an arrest of development at an infantile or immature stage; hence the small stature of the Veddah (the average male measures only 5 ft. in height), the tendency to the suppression of hair on face and body, the short, wide face, and in particular the small head and brain. In their physical appearance, the Veddahs are quite unlike the Bushmen of South Africa, and yet Prof. Osman Hill finds the two races have many cranial characters in common, most of these being of an infantile nature. The last racial census of Ceylon (1921) gave the Veddah population as 4,510; the numbers are decreasing rapidly; Sinhalese on one side, Tamils on the other, are filtering into Veddah country, with the result that hybridity is becoming common. Indeed, Prof. Osman Hill finds it necessary, on this account, to reject many skulls which have hitherto been accepted as pure Veddah.

Rays and their Allies from the Eastern Pacific

A most useful account by William Beebe and John Tee Van of the rays, mantas and chimæras collected by the Eastern Pacific Expeditions of the New York Zoological Society has been published (Fishes from the Tropical Eastern Pacific. Part 3. Contribution No. 630, Department of Tropical Research, New York Zoological Society, *Zoologica*, Oct. 1941). This paper is concerned with collections from several expeditions and contains keys to the families of rays and mantas of the tropical eastern Pacific and to the genera and species. Forty-three rays and two chimæras are described with figures. Range, colour notes, field characters, size, local distribution, abundance, food and breeding are included in the description of each species whenever possible. The food notes are interesting. It is shown that several rays eat polychæte worms and small shrimps. *Narcine entemedor* had in its stomach "a pure culture of red polychaete worms, armed with strong spicules". *Discopyge ommata* fed on Amphipods, small shrimps and worms. This ray has a very conspicuous pattern and gives fairly strong electric shocks. Several species contained young in various stages of development and in others there were egg cases. A female manta or sea-devil captured at the Galapagos Islands was eighteen feet in width and had an embryo 28 in. across, the disk with its tail protruding from the parent and the yolk sac almost absorbed—almost ready to be born.

Young Pacific Sailfish

William Beebe has described two very young sailfish (*Istiophorus greyi*), one of which is the smallest ever seen (Eastern Pacific Expeditions of the New York Zoological Society. XXVII. Contribution No. 629. Department of Tropical Research. New York Zoological Society. *Zoologica*, 26. Part 3, Nos. 19–27; 1941). These were taken on the Eastern Pacific *Zaca* Expedition (1937–1938), one off the western coast of Mexico, 3¼ in. long, which came up to the submerged light at night over a depth of about 67 fathoms, the other 1,200 miles to the south-east, off Costa Rica, 1⅝ in. long, taken in similar circumstances. The detailed descriptions of these two fishes are of great interest, as are also the notes on colour, habitat and especially the food. Externally they resemble the adult, having already a greatly elongated upper jaw and pelvic fins and enormously expanded dorsal fin. Internally, however, they are very different; their jaws are provided with quite ordinary teeth and the body is covered with scales. The whole skeleton must undergo a complete change and this is probably mainly due to the very different form of feeding and feeding movements. A comparison is made with a young Atlantic sailfish (*Istiophorus americanus*), and it is shown that the food is similar. In each species it was mainly copepods, all small Cyclopoida belonging to the tropical surface forms, and a very young fish, in one case certainly, in the other probably, a clupeoid. The fish were bitten in two and the copepods swallowed whole. The food of an adult *I. greyi*, also from the *Zaca* Expedition and weighing 115 lb., was seven small and one large squid, a two-inch paper nautilus, shell and inmate, and a 40-mm. Chaetodon, all quite uninjured. The fact that all this material is swallowed whole and undamaged is striking, especially as the adult fish is commonly reputed to obtain its food by using its snout like a slashing broadsword.

Memory in Insects

W. H. Thorpe (*Proc. Roy. Soc.*, 127, 424–433; 1941) has shown that larvæ of Nemeritis and *Drosophila melanogaster* reared on particular media gave rise to imagos which preferred these. Thus adults of *D. melanogaster* arising from larvæ reared on media containing essence of peppermint were not repelled by the smell, as are normal cultures. J. E. Cushing (*Proc. Nat. Acad. Sci.*, 27, 496–499; 1941) has been experimenting with a pure strain of *D. guttifera* which normally inhabits fungus-infested food. He raised some larvæ on fungus-free and some on fungus-infested media, and allowed the resulting adults to choose between them for egg laying. Again the conditioning of the larvæ significantly influenced the preference of the adult. He points out that this physiological change in the life of Drosophila acts on the mechanism of populations by influencing isolation, population size and selection pressure in a somewhat similar manner to the homing of birds or of salmon or to mating preferences.

Size Inheritance in Tomatoes

J. W. MacArthur (*J. Hered.*, 32, 291–295; 1941) has used four lines of tomatoes which have been inbred for at least twelve generations to explore the manner of inheritance and effect of size genes in the tomato. By intercrossing these lines, and planting lines and hybrids in a Latin square, an analysis of the fruit weights can be made by separation of the variance due to environment (0·4 per cent), to varieties (99·4 per cent) and to error (0·2 per cent). Further, it was found that the F_1 generation closely approaches the geometric mean of the parental lines. Thus it is demonstrated that the substitution of one set of genes for another gives a geometric and not an additive effect.

Photo-decomposition of Acetone

THE photo-decomposition of gaseous acetone is apparently a complex process, ethane, carbon monoxide and diacetyl being formed at room temperature in varying ratios depending on the circumstances. A re-investigation of the process by R. Spence and W. Wild (*J. Chem. Soc.*, 590 ; 1941) has brought to light some new features. It is shown that the apparently contradictory results found in earlier research by the authors and by Herr and Noyes in the continuum region of absorption can be represented by a single expression derived from a common mechanism. A purely radical type of mechanism is shown to be excluded by results in the banded region of absorption. The effect of pressure on the quantum yield and on the ethane/CO ratio is explained by the assumption of two activated states of the acetone molecule with very different life-periods of the order of 10^{-8} sec. and 10^{-2} sec., the second being a metastable state. This mechanism is :

$$(CH_3)_2CO + h\nu = (CH_3)_2CO'$$

$$(CH_3)_2CO' \xrightarrow{10^{-8}\text{ sec.}} CH_3 + CH_3.CO$$

$$(CH_3)_2CO' + M = (CH_3)_2CO'' + M$$

$$(CH_3)_2CO'' \xrightarrow{10^{-2}\text{ sec.}} C_2H_6 + CO$$

$$(CH_3)_2CO'' = (CH_3)_2CO$$

$$(CH_3)_2CO'' \xrightarrow{\text{wall}} C_2H_6 + CO.$$

At low pressures decomposition into radicals predominates and C_2H_6/CO can reach high values, while at pressures above 100 mm. direct decomposition into ethane and carbon monoxide is the primary process. The theory is complicated. but each phase has been related to some definite experimental result. It should be noted that the excited molecule of longer life does not yield free radicals but either reverts to the normal state or decomposes into ethane and carbon monoxide.

Intuition and Higher Space

THE term 'geometry' is now used in a very wide sense, and some mathematicians feel that there is an essential difference between that of one, two or three dimensions, in which spacial intuition is of great value, and modern extensions to four, five, or even an infinite number of dimensions. A method for the graphical representation of these higher kinds of spaces has now been given by M. Randall and B. Longtin (*J. Washington Acad. Sci.*, 31, 421 ; 1941). For n dimensions we replace the desirable but unattainable n mutually perpendicular axes by n parallel lines on a sheet of paper, so that a point in space of n dimensions is represented by n points on the paper. It is easy to pass to functional space of an infinite number of dimensions, for the point in functional space is represented by a continuous curve. Two applications of the methods of this paper are of some importance. They can be applied to the study of processes for separating the components of a mixture of several chemical compounds, and to the determination of the intensity of luminous energy concentrated in each wave-length of a spectrum.

Origin of Planets and Satellites

IN a paper on this subject (*Mon. Not. Roy. Astro. Soc.*, 101, 7 ; 1941), R. A. Lyttleton introduces certain modifications in the results that he had previously obtained. In some of his earlier papers he showed that in the evolution of a primitive rotating planet, when a state of instability was reached, the division produced a pair of masses of mass-ratio 3 : 1 approximately. In dealing with the gravitational energy of the critical ellipsoid, Lyttleton used a numerically incorrect value which led to the above ratio, but the use of the correct value shows that the mass-ratio must be at least 6 : 1 and possibly higher. In these circumstances it does not seem possible that Jupiter and Saturn should have originated from a single mass, as previously suggested, unless the initial mass-ratio has been reduced as a result of some increase of mass by these planets since this stage of their formation. Various lines of evidence suggest that such an increase could occur, though there is nothing to show that any of these alleged factors were actually effective. The modification introduced does not necessarily exclude the method of formation of the terrestrial planets and of the satellite systems of the great planets, which Lyttleton had suggested in his earlier papers, but it opens up the possibility of other ways in which various pairs of planets may be related. Of these the simplest situation would be obtained on the supposition that two primitive planets evolved by fission to produce Jupiter and Neptune, say, from one of them, and Saturn and Uranus from the other. It is admitted, however, that all four planets may have had separate origins, and other possibilities exist between these two cases.

Spectrophotometry of the Night Sky

THE intrinsic brightness of the night sky sets a natural limit to the photography of distant nebulæ with large modern reflecting telescopes. If the spectral distribution of the radiation from the nebulæ approximates at all closely to that of the light from the sky, we can expect no improvement of this position by the use of such devices as colour filters. However, the light from the nebulæ is made up largely of starlight little different in quality from sunlight, whereas most of the night sky radiation is terrestrial in origin and is similar to auroral light ; there may thus be a difference in spectral distribution which could be exploited in astronomical photography. H. W. Babcock and J. J. Johnson have now compared the energy distribution in the light of the night sky with that in the Andromeda nebula (*Astrophys. J.*, 94, 271 ; 1941). Spectra of both sources were obtained on Mt. Palomar with a quartz spectrograph fitted with an *f*/1 Schmidt camera and attached to a 12-in. reflecting telescope. Each spectrogram was separately standardized with a standard lamp operated at 2580° K. The spectral energy curves are roughly parallel from the red down to about 4500 A. From there to about 3200 A., however, the night-sky intensity remains constant while the nebular intensity drops sharply. It is therefore suggested that improved contrast in the direct photography of nebulæ can be obtained by using a filter to remove the unwanted ultra-violet light. This procedure is especially necessary when the elevation of the telescope is small, since the nebulæ are then reddened by atmospheric absorption, while the night sky is brightest at low altitudes.

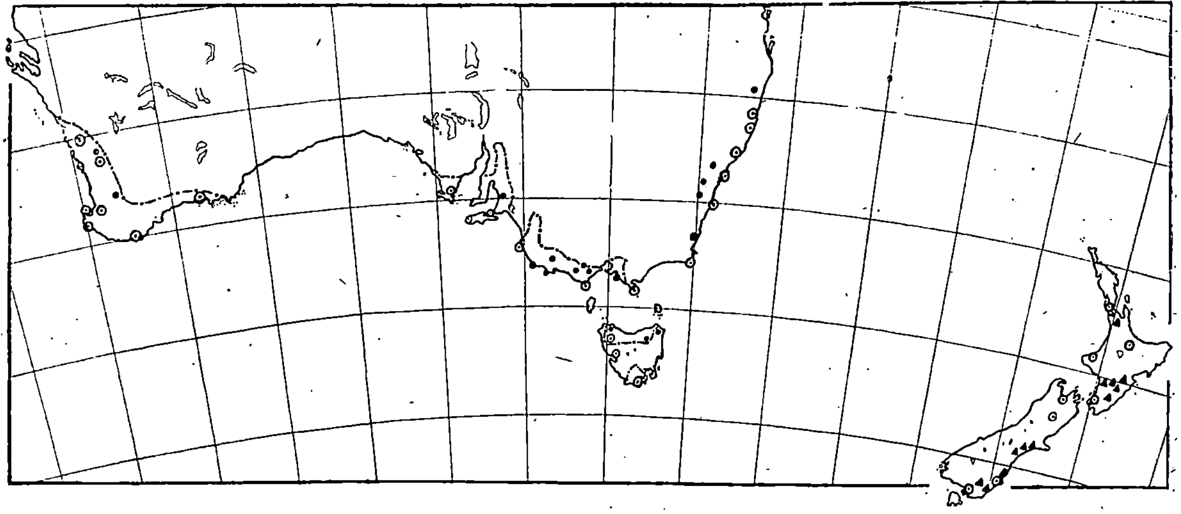
THE PREDICTIVE METHOD IN ANIMAL ECOLOGY

By DR. D. STEWART MACLAGAN

Department of Zoology, University of Durham

EVERY scientific problem resolves itself into a quest for the relationship between two or more variables. The discovery of these inter-relations provides the basis for prediction and control, so important in the applied aspects of a science, and bespeaks the entry of the latter into the highest phases of its development. Although biology is one of the younger sciences, it has made such great advances in the descriptive phases that further developments are taking place along quantitative lines, with the ultimate objective of *predicting* the organic response to given conditions. The methods elaborated by the animal ecologist for the forecasting of biological events in time, or in space, are still comparatively rough hewn, and certain fundamental principles will have to be taken as proved, for the present, since lack of space prohibits presentation of the ever-increasing mass of evidence upon which they are based.

The first is that populations of animals are controlled by a complex of environmental factors which are continually varying in intensity, both spacially and chronologically; and of which the climatic factors play the dominant part in the initiation (but not always in the termination) of the condition known as an epidemic or 'plague.' The second is that, although numerous factors operate simultaneously to retard population-increase in Nature, there are great differences in the relative significance of the various phases of the life-cyle, in so far as numerical increase of a species is concerned, so that 'critical' periods can be recognized. Thirdly, the critical periods are usually associated with the early stages of existence or with reproduction. The primary task of the biological forecaster, therefore, is the discovery and climatological delineation of critical periods in the life-cycle, such periods resulting from the high susceptibility of certain stages or processes to deviations from a narrow optimal range. These ecological concepts synthesize my views as the result of investigations conducted over a period of twelve years, and it is of interest to find that the predictions which were ventured in some of the earlier researches have been vindicated by recent experience, as follows:



From 1928 until 1930, a detailed ecological study of the collembolan, *Smynthurus viridis* L., was undertaken, at the Parasite Laboratory of the Imperial Institute of Entomology.[1] Utilizing field data in combination with the results of planned laboratory experimentation upon the 'field physiology' of the insect, an attempt was made to determine: (1) the complete geographical range of existence of the insect, (2) where it would cause damage of economic significance every year, and (3) where it would become of economic importance occasionally. On analysing the environmental controlling complex of Smynthurus, it was ascertained that the minimum rainfall for existence of this species is the minimum rainfall for oviposition, namely 0·12 in. a month, because the moisture requirements of this process are higher than those of any other process or phase in the life-cycle. The upper rainfall limit is approximately 7·0 in., due to fungus and bacterial attacks on the eggs, under conditions of excessive moisture. The upper temperature limit for the species is the maximum which can be tolerated by the stage least tolerant of high temperatures, namely, the embryonic nymphs, which cannot survive mean temperatures exceeding 66°F. The other temperature extreme is determined by the stage the activity of which ceases first when the temperature falls, and this is the egg, its threshold of development being approx. 44°F. Optimum conditions for multiplication of Smynthurus occur when there is a monthly rainfall of 3·1–6·0 in., together with a mean monthly temperature of 52°–57°F. The damage to lucerne and clovers becomes of economic significance when these conditions obtain for two consecutive months. Further, the areas in which the insect becomes of economic significance occasionally are characterized, in general, by a monthly rainfall of not less than 2·5 in. combined with a mean monthly temperature of 51°–58°F., exclusive of the areas which conform to the requirements of the optimum environment.

Based upon the above criteria of favourability, a map was prepared to illustrate the predicted geographical *range* of Smynthurus and the areas of probable *economic* significance. As a result, it was stated (*loc. cit.*, p. 181)—"it is evident that there are several

DISTRICTS COLONIZABLE BY *Smynthurus viridis* L., (1) FAVOURABLE, (2) HIGHLY FAVOURABLE.

New Zealand	Many stations	Auckland, New Plymouth, Wellington, Dunedin, Invercargill, Rotorua, Nelson, Hanmer, Gore
W. Australia	Guildford, Perth, Northam, Narrogin	Watheroo, Albany, Bridgetown, Bunbury, Cape Leeuwin, Cape Naturaliste, Collie, Esperance, Karridale, York
S. Australia	Adelaide, Cape Northumberland	Port Lincoln, Cape Borda, Kingscote, Robe
Victoria	Cowes, Colac, Hamilton, Portland, Terang	Gabo Island, Wilson's Promontory, Lorne, Cape Otway
N.S. Wales	Lismore, Maitland West, Bowral, Parramatta, Adelong	Kempsey West, Port Macquarie, Sydney, Jervis Bay Nowra, Moruya Heads
Tasmania	Stanley, Eddystone Point, Zeehan, Launceston	Hythe, Cape Sorell, Waratah, Currie
	(1)	(2)

countries to which Smynthurus is potentially a serious economic menace, the most important being New Zealand, the south-west corner of Cape Province, Natal, Chile, New South Wales, and the United States of America". At the same time, an attempt was made to portray, in greater detail, the limits of existence and of economic significance of the insect in Australia, on account of its known depredations in Western and South Australia. This led to the conclusion (*loc. cit.*, p. 183), "that there is a large tract of country in New South Wales and southern Victoria from which the insect has not yet been recorded, but to which, in the event of its introduction, it would undoubtedly prove to be a serious economic problem. Also, there exists a fairly large band of territory in the north and western parts of Tasmania which is highly favourable . . . although the insect . . . has not yet had time to demonstrate its full potentialities as regards numerical increase". In view of recent reports upon the economic status of Smynthurus, these statements are of considerable interest to biologists in general and to ecologists in particular.

Thus, commenting on the lucerne flea in Tasmania, Evans[2] says: "it was introduced about 14 years ago and is now responsible for extensive damage to pastures"; whilst Pescott[3], discussing the colonization of Victoria by the species, remarks that this "introduced insect, was, until several years ago, confined to the coastal areas of the Western District of Victoria, but recently it has been found scattered over other portions of the State". Entomologists of the Australian Council for Scientific and Industrial Research[4] report that the pest now occurs "in isolated areas in other districts in this State [Victoria] and in southern New South Wales". The situation in New Zealand has been summarized recently by Dumbleton[5], thus, "In the North Island, the lucerne flea is known to be widely distributed in an area including Bulls, Palmerston North, Dannevirke, Woodville and Eketahuna. There is one isolated occurrence of the flea near Pokeno and another near Maraekakaho. In the South Island, the insect was found to be present over an area including Temuka, Timaru, Waimate, Oamaru, Mosgiel, Balclutha and Gore."

Hence, the predictions ventured by me in 1932 have materialized sooner than I expected. The accompanying map indicates, by means of dotted lines (Australia), and by triangles (New Zealand), the known distribution of the insect in numbers of economic significance; while the climatically favourable and highly favourable areas (based on the original climatic criteria) are represented by means of a dot and a dotted circle, respectively. It is my belief that prediction of the abundance and distribution of animal-populations is a field of scientific endeavour which will yield results of great interest and value. With the co-operation of biologists and meteorologists this branch of ecology should be one of the most powerful weapons in the armoury of the economic biologist.

CONDITIONS IN FACTORIES

IN a paper "Factory Inspection: a thirty-five years' Retrospect", given before the Royal Statistical Society on May 20, which has now appeared in the *Journal of the Royal Statistical Society*, Sir Duncan Wilson gives a most interesting picture of the developments under the Factory Acts leading to the prevention of accidents and the elimination of industrial disease, as well as indicating points at which statistical information is still lacking or incomplete. Between 1904 and 1938 the staff of the inspectorate more than doubled. Sir Duncan Wilson paid a warm tribute, which was endorsed in the subsequent discussion, to the way in which from the start the factory inspectors, relying on education and persuasion rather than on the full exercise of their statutory powers, had secured the co-operation of employers and managements. In the same period the expenditure had more than trebled and the figures quoted by Sir Duncan Wilson emphasized the huge increase in the use of mechanical power. While the number of factories has increased by about 70 per cent, the number of workshops or places without mechanical power has been reduced to about one half. The data show that industrial diseases have been fought with much greater success than accidents. Fatal accidents per 100,000 employed decreased from 17·6 in 1904 to 11·2 in 1938 and this decrease may be taken as a measure of the severe accident rate. On the other hand, reported accidents almost doubled in the same period. As the criteria were more stringent in 1904 the difference is much greater than would appear from the actual figures.

Sir Duncan Wilson notes that, although of late the proportion of very large factories has increased, about one third of the working population is accommodated in factories employing not more than a hundred workers and more than one half in factories employing not more than two hundred and fifty workers. The chief work of the factory inspector in fact lies in quite small factory units and the trouble there, as Mr. A. W. Garrett pointed out in the discussion, is that there is often not the broad outlook which characterizes the management in the larger concerns. Sir Duncan also directed attention to the high incidence of accidents among young workers under eighteen.

Statistical treatment of the available data over the period explored indicates a distinct tendency for the numbers employed to rise associated with a smaller tendency for accidents generally to rise and with a tendency for fatal and presumably other severe accidents to fall. The two curves are roughly parallel, variations in numbers employed being positively associated with similar variations not only in the mere numbers of accidents but also with the risk of incurring them. Of the more personal aspects of industry, Sir Duncan does not think that the loss of paternalism involved in modern times in the formation of large combines replacing or absorbing the small employers is a pure loss, but emphasizes that many and probably most of the small employers were first concerned with profit and lastly with the safety, health and general interests of their workers. He refers to the noticeable change in the workers themselves and asserts that the bedraggled, ill-mannered and ill-spoken worker has been replaced by one with self-respect, good appearance and the best manners of any social class. Sir John Forbes Watson, in the discussion which followed, referred to the importance of the analysis of factory conditions in Great Britain as compared with others and the importance of developments in industrial medicine was stressed by Dr. H. B. Morgan, who paid a particularly warm tribute to the work of the factory medical inspectors. Mr. Robert R. Hyde, director of the Industrial Welfare Society, in a written communication, referred to the importance of ways and means of providing the smaller units of industry with some form of the medical service which has already been developed with such success in many large firms.

RECONSTRUCTION AND ECONOMICS

IN a pamphlet entitled "Post-War Poverty and Unemployment Can be Prevented" issued last year (see NATURE, 146, 312; 1940) T. W. Wyatt and D. Caradog Jones challenged the assumption that a period of intense economic depression and serious unemployment is bound to follow the War, and urged that, on the contrary, it should be possible by a carefully thought-out plan, co-ordinating all forms of industrial activity, to change over from war production to peace production, utilizing the vastly improved capacity of production for creating new wealth. A postscript by J. R. Bellerby outlined five stages by which this could be achieved. Messrs. Wyatt and Caradog Jones have now, under the title "Britain's New Order"*, issued as a sequel a further thoughtful study of methods of preventing post-war unemployment, which deals with some of the questions and doubts raised by their earlier pamphlet.

The pamphlet urges that local authorities should be encouraged to prepare schemes of work to put into operation as soon as ever private demand slows down after the burst of activity which may be anticipated immediately after the War. Government departments which are able to do so should set an example by initiating public works when the suitable moment arrives. The appointment of a commission with members drawn from all walks of life and responsible to Parliament is suggested to decide which schemes of public work should have preference and to regulate the purchase of surplus foods and materials for storage in different parts of the country. The criterion for determining the approval of or vetoing of any particular scheme should be its consistency with, or opposition to, the public interest. Every effort should be made to decentralize as much as possible and to interfere as little as possible with private initiative, subject only to the over-riding conditions that the national and municipal interest must come first.

Messrs. Wyatt and Jones urge that modern powers of production are so vast that they must be regulated or they will overwhelm us. It is within our power at the end of the War to build a new world, but we must scrap our old impressions of scarcity and of the need for all-round sacrifice to pay for the War. Taxes, accordingly, they consider should be made as light as possible, and they should be raised or lowered solely for the purpose of regulating purchasing power.

Money or credit required to keep production and exchange functioning should be created directly by the Government up to a strict limit when labour, machinery and materials were all fully and efficiently employed. This demands a high degree of skilled organization for which training and time may be required, and although Messrs. Wyatt and Jones believe that no radical change in the present economic system is required, they point out that sudden transition from a system based on production for profit to a new system based on production for use would be dangerous. The present system can be made to provide a much higher standard of life than we have hitherto enjoyed, and this higher standard will permit us to acquire the better education which is the pre-requisite for the organization of a more rational and efficient system of production for use and service.

All the machinery for a great forward stride, given the right direction and control, is at our command. The large surpluses of all kinds of commodities which are piling up in various parts of the world are as important to the countries of their origin as to those that receive them. Much of the urgent reconstruction required over a wide area will be completed in a relatively short time, and all this work must be undertaken regardless of cost. Purchasing power is the key to distribution, and the solution of the problem of distribution will remove one of the most potent obstacles in the path of a settled peace.

In their attempt to build on past experience, the authors are undoubtedly in keeping with the British tradition, and the work which it is proposed should be entrusted to a Parliamentary Commission is already largely in the hands of the Cabinet Committee under Mr. Arthur Greenwood, the Ministry of Works and Building, or the Leith-Ross Bureau.

Essentially the same ideas are outlined in two articles which have appeared in the October number of the American periodical *Fortune*. In the first of these, Mr. Geoffrey Crowther, editor of the *Economist*, at present visiting the United States, enters a powerful plea for a political democracy which includes a balance, and not merely a mixture, of the social and the profit motives. Mr. Crowther suggests, for example, that the whole of the question of food supply should be removed, in peace as in war, from the operation of the profit motive, and the incentive of order, or purposeful organization by the community, substituted for that of freedom and private profit, in much the same way that education is already organized on a service basis. The concept of social security, however, should not be limited to the satisfaction of basic needs. The extended Bill of Rights must be accompanied by an extended Bill of Duties including specific social service, whether in the defence forces, the health services, or in whatever special sphere the particular citizen may be best qualified to serve.

---

* Britain's "New Order": a Plea for a Sane Post-War Employment Policy. By T. W. Wyatt and D. Caradog Jones. Pp. 32. (Birkenhead: John Woolman and Sons, 1941.) 9*d*.

Such service would very materially ease the financial burden of the Citizen's Charter, and Mr. Crowther then suggests that over the remaining half of the national economy where the incentive of profit would continue to function, subject to the watching brief of the Government as trustee for the community, it is important to take the brakes off enterprise, and stimulate economic activity with the view of stimulating employment. The profit motive, he urges, is in dire need of assistance, and like Wyatt and Jones, he attacks the policy of excessive taxation as well as repression of enterprise or individuality through monopolies, cartels, trade associations, or the like. When the basic needs of the citizen have been met and his strongest fears removed, it is in an atmosphere of freedom that the human spirit can develop its full powers, and he contends that it should be possible for both the Left and the Right to accept a balance between freedom and order.

Mr. A. A. Berle, jun., Assistant Secretary of State, in an article on post-war development, urges that every defence industry should have a research staff working on plans for producing peace-time goods. A conference should be held to take inventory of these plans and to lay out a catalogue of the products that will be available when the War ends. This catalogue should be matched against known needs of the country for reconstruction, including such needs as relocation and modernization of city areas, new housing for several millions of families, public works, and nutrition, adequate in kind and quality to ensure public health. These needs are potential markets. Out of these and others like them there should be constructed markets sufficient to ensure full use of our plants and full employment for all our people.

Finance, Mr. Berle argues, is a technical problem, like engineering. We can afford anything for which we have materials, labour and reasonable needs. These are the only stop signs, and common-sense adjustment of war finance to peace finance will permit construction of markets to the extent necessary. Like Messrs. Wyatt and Jones, Mr. Berle is convinced as to the richness of the new era that modern technique puts within our reach, and he concludes with the reminder that economics tends to reflect the desires and wants of a country, and whether our new order is to be an enduring and stable order will depend above all on its moral basis.

FORTHCOMING EVENTS

Saturday, January 24

British Rheologists' Club (in the Department of Physics, The University, Birmingham), at 1.15 p.m.—Discussion on "Classifications of Rheological Properties".

Monday, January 26

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. B. A. Keen, F.R.S.: "Soil Physics, Theory and Practice" (Cantor Lectures, II).

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 3 p.m.—Kodachrome Films by Mrs. Patrick Ness: "Burma, Indo-China, Thailand and Netherlands Indies".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5 p.m.—Discussion on "Is there an Electrical Basis for Water Divining?" (To be opened by Mr. J. F. Shipley).

Wednesday, January 28

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C,2), at 1.45 p.m.—Mr. F. R. Yerbury: "The Post-War Home—Its Interior and Equipment", 4: "Adaptation of Design to Standardisation and Mass Production".

Institute of Physics (London and Home Counties' Branch) (at the Royal Institution, Albemarle Street, London, W.1), at 2 p.m.—Conference on "Electronics" (Chairman: Prof. J. D. Cockcroft, F.R.S.).

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 4.30 p.m.—Annual General Meeting. Sir George Simpson, K.C.B., F.R.S.: "The Electricity of Cloud and Rain" (Presidential Address).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Civil Engineering Assistant experienced in Land Drainage Works—The Clerk to the River Trent Catchment Board, Catchment Board Offices, Derby Road, Nottingham (January 30).

Borough Electrical Engineer—The Town Clerk, Town Hall, Burnley (endorsed 'Borough Electrical Engineer') (January 31).

Lecturer in Electrical Engineering—The Principal, County Technical College, Guildford, Surrey (January 31).

Lecturer in Mechanical Engineering—The Principal, Handsworth Technical College, Golds Hill Road, Handsworth, Birmingham 21.

Lecturer in Electrical Engineering—The Registrar, Wimbledon Technical College, Gladstone Road, London, S.W.19.

Lecturer in Mechanical Engineering Subjects—The Principal, Kingston-upon-Thames Technical College, Kingston-upon-Thames, Surrey.

SCIENTIFIC ORGANIZATION OF SOCIAL ACTIVITIES

EXPERIENCE has indicated that some of the economic and social activities of a nation cannot safely be left to unguided individual initiative or interest. Education has long been reckoned as such a social activity, and most of the effort required to supply the essential needs comprised in the idea of the social minimum and embodied in what has been described as a new Bill of Rights for the citizen might be placed in the same category. Mr. Geoffrey Crowther, editor of the *Economist*, in an article in the American periodical *Fortune*, goes so far as to suggest that all activities connected with the supply of the nation's food, including production, as agriculture, and distribution and processing, should be planned and controlled by the nation in order that the new standards of nutrition, etc., may be secured. The magnitude of the problem suggests at once that it is by no means easy to draw a line beyond which the profit motive should not be permitted. It may be conceded, for example, that public health is definitely a matter for purposeful organized effort on behalf of the community and cannot be left to the operation of the profit motive. The implications of such a policy, however, are far-reaching and not all obvious. National health is the product of many factors, and some of them, not the least important, owe their primary stimulus, not necessarily, indeed, to the motive of profit or private gain, but certainly to that element of freedom which Mr. Crowther suggests should in theory be excluded from the social field.

The health of the community does not depend only on the general state of nutrition and the standard of living, including all those environmental factors involved in town and country planning, recreation, the location of industry, industrial welfare and the like, and on the social services, such as the health services themselves, whether preventive or remedial. These activities are clearly those which should be planned and run by the community with no consideration of profit and with the main object of effective service to the needs of the community. The public health depends further on the prosecution of scientific research, not merely into nutrition but also into the prevention and cure of disease, and it is at this point that, as is indicated by Sir Henry Dale's recent presidential address to the Royal Society and the recent announcement of the formation of the Therapeutic Research Corporation, there is a definite need for a mixture of the motives of freedom and service. Sir Henry Dale laid the major stress in his address on the importance of freedom and opportunity rather than organization as providing the conditions for the highest type of research. None the less he recognizes the necessity of organization if discovery is to be put to full use, and his example of the association of science with the State without weakening the freedom of the scientific worker so happily illustrated by the Medical Research Council indicates that balance between order and freedom for which Mr. Crowther pleads. Sir Henry holds that the existing mechanisms for the support of science by the State, while susceptible of improvement, offer no threat to the freedom of science, nor does the wider use of the organized application of science and scientific method to problems of public welfare, or the more effective access of scientific knowledge to those responsible for government.

The train of thought started by Sir Henry Dale and Mr. Crowther thus raises the very pertinent question as to whether the organization of medical and pharmaceutical research is not a matter for the State acting on behalf of the community, and whether after the War the field of activity of the Medical Research Council should not be extended so as to remove or limit considerably the operation of the profit motive in this field. The subject is one which is ripe for fuller consideration, but it must be remembered that in this field the past experience of Government organization or direction does not warrant undue optimism as to the advantage of a radical change in policy. The related field of industrial health supplies a pertinent example.

A recent report of the Select Committee on National Expenditure commented on the neglect to make full use of the Industrial Health Research Board for the scientific study of questions affecting industrial health and the best use of labour. The Government comment on a specific recommendation regarding investigations on the best length of the working week, while accepting as a basis for action the results of the Board's investigations, and indicating that it is proposed to obtain information as to sections of industry or particular kinds of work into which the Board might make further investigations, does not touch the root of the Select Committee's criticism—the inadequate resources and staff of the Board. On this point the recent report of the British Medical Association's Committee on Industrial Health in Factories is far from reassuring; that it should be possible for such a report to characterize industrial health research as on the whole sporadic and unco-ordinated, reflects neither to the credit of Government or people.

The B.M.A. Committee is clearly right in holding that further effort is required to place industrial health research on an adequate and efficient basis. If we have due regard for the national health, we cannot tolerate a system which fails to provide essential staff for the Industrial Health Research Board, or requires its paid secretary to act also as chief medical officer to the Ministry of Supply, and relies too much on incidental research of the medical inspectorate of factories. In the absence of driving force from the Government, we cannot be content to leave research in this field to the medical departments of individual firms.

Whether a fresh organization should be established for this purpose, as recommended by the B.M.A. Committee, is quite another matter. The logical method would be to develop the national organization which already exists, and extend the work and resources of the Industrial Health Research Board, linking up its work with regional schemes or organizations covering particular industries as required. The contacts already established with individual firms should provide a starting-point or nucleus for further development, and the co-ordination and application of the knowledge already available is unquestionably a matter for the State.

There will be general agreement with the Committee as to the urgency of the matter, and if preoccupation with other matters is the only legitimate explanation, though no excuse, of the Government's neglect of the many problems in this field of the utmost importance to the nation's health that are awaiting solution, the stimulus must come in the first instance from the professional workers concerned. Not merely the medical practitioner but also others concerned with the problems of industrial health—the manager, the chemical engineer, the plant superintendent, the chemist, the labour manager, individually and through their professional associations, must address themselves to the task of educating both the Government and Parliament, as well as the nation at large, to the importance and urgency of these questions from the point of view of our maximum war effort as well as of the long-term health of the nation.

It is, indeed, on the faithfulness and earnestness with which scientific workers turn to this and like tasks of education that the effectiveness of reconstruction and the wider possibilities of a new order largely depend. Reconstruction and the new order to be established after the War will be conditioned—and limited—by the extent to which public opinion is prepared for the necessary changes and understands what is involved. The contribution of the scientific worker in this task of education is, indeed, far more vital than any contribution he may make in the actual administration of the schemes put into operation. Scientific workers as such have no special claims for administrative responsibilities, though their scientific qualifications should not, as so often happens, debar them from administrative office when they clearly possess, in addition, administrative ability. They do carry, however, a special responsibility for sharing in the task of educating the community to an intelligent understanding of the technical or scientific factors involved in public problems concerning health or in any other field.

The report of the Committee on Industrial Health in Factories, and also the formation of the Medical Planning Commission, show that the British Medical Association has under consideration a number of these urgent problems. Some other professional associations, such as the Royal Institute of British Architects the Institute of Physics and the Institutions of Civil and of Mechanical Engineers, are also seeking to focus attention on the problems that lie immediately ahead. There are other categories of scientific workers who are far from showing signs of being asleep, even on matters not intimately connected with their own profession. The report on industrial health in factories, for example, contains the rather naïve suggestion that an industrial medical officer should be responsible directly to the managing director of his firm, and its proposals for a central advisory body to guide employers in making appointments may well meet with some criticism from within the profession.

It must, in fact, be admitted that scientific workers and other professional men are not necessarily able to take detached or objective views on matters of public policy that affect their own interests, nor even to apply scientific methods to problems outside the highly specialized field in which they are themselves engaged. No less than other sections of the community, they require educating, at least in outlook, and their professional associations, taken as a whole, are representative of conservative rather than of progressive elements. The responsibility for undertaking the task of education, whether within or without the ranks of the profession, lies the more heavily accordingly on the shoulders of those scientific and professional men who are awake to the needs and implications of the present situation. Whether or not the hopes that have been raised of a new and more bounteous world order are to be realized depends largely on the way in which this task of education is undertaken now. The Conference on Science and World Order held last September, the Conference on Science and the War Effort held in January, and the formation of the Medical Planning Commission of the British Medical Association are welcome signs that the task is already being undertaken.

MODERN THEORIES OF ORGANIC CHEMISTRY

Modern Theories of Organic Chemistry

By Dr. H. B. Watson. Second edition. Pp. viii+268. (Oxford: Clarendon Press; London: Oxford University Press, 1941.) 17*s.* 6*d.* net.

AT the present time organic chemistry is enjoying one of its recurrent periods of profuse activity: an activity manifest in two main directions. In the first, great and impressive advances are being made in the difficult task of unravelling the molecular structures of complex compounds of profound physiological and biological significance. A second characteristic feature of modern organic chemistry is its growing concern with the mechanism of reactions, and great efforts are being made to reach an understanding and eventual solution of this group of problems. In their elucidation the methods of physical chemistry and of physics find as much, if not more, application than do the classical methods of organic chemistry.

This peaceful penetration of the rich and fertile provinces of organic chemistry by the ideas and experimental methods of physics and physical chemistry has been steady and persistent during the last few decades, while in more recent years the pace has quickened. Both branches of chemistry have gained thereby and abundant material becomes available for an interesting story.

The four years which have elapsed since the publication of Dr. Watson's well-known volume have witnessed notable developments on the theoretical side of organic chemistry, and concise summaries of these have been woven into the fabric of the new edition now under review. The new edition, however, does more than incorporate new material: large sections have been carefully re-written and reference rendered easier by the more abundant use of sub-headings. Further, the order of treatment of various subjects has been revised, leading to improvements both in classification and logical sequence. Topics formerly omitted or merely mentioned in passing, probably being regarded as in too early a stage of development for a balanced review in the old edition, now take their appropriate place in this admirable survey, which covers a wide field in considerable detail. Despite its detail, it is a most readable book; its perusal is greatly helped by clearness of print and orderly arrangement of formulæ. The opening chapter now includes an extension of the earlier section on quantum mechanical resonance and its application to resonance between different bond structures, mesomerism and the stability of the hydrogen bond.

Chapter 4 includes notes on electron diffraction and molecular magnetism, particularly valuable in view of the important parts which these methods may be destined to play in the elucidation of molecular structure. The discussion of dipole moments, now arranged in a more coherent manner, is included in this chapter and its value enhanced by the inclusion of some of the more recent results brought to light by this line of inquiry. Similarly, the general discussion on the applications of the electronic theory of valency to organic chemistry, now forming Chapter 6, is arranged in better order and includes a description of the most recent experimental results and speculations; the account of mesomeric, electromeric and inductomeric effects, rather involved in the old edition, has been clarified and amplified.

A new chapter on esterification and hydrolysis gives an outline of the development of the current theories of these reactions; while the interesting subject of simple substitution reactions in aliphatic compounds, so exhaustively investigated during the past few years by Ingold, Hughes and their co-workers, deservedly receives full discussion in a further new chapter.

The chapter dealing with reactions in which the primary process involves addition to unsaturated compounds is enlarged and describes modern views on the mechanisms of the Knoevenagel, Perkin, Claisen and aldol reactions.

The increased space, now amounting to three chapters, devoted to stereochemistry is an indication of the greater interest being taken to-day by the general organic chemist in this important subject. It includes a concise but adequate account of the Walden inversion—a notable omission from the first edition but a welcome addition to the second—a discovery for long regarded as a kind of chemical Cinderella but the further investigation of which has yielded so much valuable information bearing on the mechanism of replacement reactions. This is followed by a short description of the application of kinetic methods to stereochemical problems together with a judicious review of current theories on the mechanism of reactions which involve a change of molecular configuration.

The new edition contains some fifty pages more than the old; despite this increase in size and the present difficulties of publication, the price of this excellently produced book has been raised by only half-a-crown; for this achievement the publishers deserve our congratulations.

J. KENYON.

THE MAMMALS OF INDIA

The Fauna of British India: including Ceylon and Burma

(Published under the patronage of the Secretary of State for India.) Edited by Lt.-Col. R. B. S. Sewell. Mammalia, Vol. 2: Carnivora (continued from Vol. 1), Suborders Æluroidea (part) and Arctoidea. By R. I. Pocock. Pp. xii+504+12 plates. (London: Taylor and Francis, Ltd., 1941.) 35*s*.

THE volumes on mammals by Blandford in the first edition of "The Fauna of British India", have long been out of date and the large amount of new material has called for a new edition. Mr. R. I. Pocock, whose knowledge of the subject from long experience, both at the British Museum and the Zoological Gardens, is second to none, has now produced the second volume of the second edition, the first, by the same author, having been reviewed in NATURE of February 3, 1940, p. 164.

As in Vol. 1, the author has shown great thoroughness and an infinite amount of careful research. He continues with the order Carnivora, commenced in Vol. 1, and deals with the families Herpestidæ, Hyænidæ, Canidæ, Ursidæ, Ailuropodidæ, Ailuridæ and Mustelidæ. One is struck by the minuteness of the details investigated by Pocock, who has not overlooked characters which former authors, with less opportunities, have missed; and not only has he described such characters, many of which have proved of value in classification, but he has also skilfully illustrated them by line drawings, those of the soft parts being mostly from fresh specimens that had died in the Zoological Gardens. His drawings of the whole animals are also very good and show the characteristic attitudes and markings of species of which no photographs are available; but it seems a pity to adopt this method of illustration where good photographs could have been obtained, such as in the case of the giant panda.

Of this strange and interesting animal the author has a good deal to tell us, though he admits that it has not yet been discovered within the precincts of British India. It was, however, referred to by Blandford in the original edition of the present work, and there seems a possibility of its turning up in the near future in Upper Burma. Moreover, we are told of a closely allied and recently extinct species of which a complete skull was found in Upper Burma.

The arrival in Great Britain of living specimens of the giant panda a few years ago caused no little sensation, as it was supposed to be one of the rarest mammals in the world. It is a carnivore that has adopted an entirely vegetarian diet, its principal food consisting of the shoots and stems of bamboo up to half an inch or so in diameter which its powerful jaws enable it to chew with ease. It was interesting to watch the method of feeding adopted by those at the Zoo, and to notice the way the shoots were firmly held in a front paw as easily as a monkey holds food in its hand. In order to enable this bear-like creature to use its front feet as hands these have been modified by the provision of "an accessory lobe which covers the tip of a slightly movable elongated bone developed from the carpus and lying alongside the metacarpus of the first digit, and completely enveloped in the skin of the paw so as to be entirely invisible without dissection".

In a book of this sort, containing as it does a mass of detail invaluable to systemists though less interesting to the general reader, it is good to find full accounts of the habits of the animals where these are known.

Mongooses are represented in India by a number of species the habits of which seem to be very much the same in all. They somewhat resemble stoats in being alert, usually fearless creatures with the habit of sitting erect on their hind quarters to increase their range of vision. They are superior to cats in the matter of vermin killing, as they can enter the burrows of their prey and dig it out, and they fearlessly attack snakes and other pests which cats will not deal with. If captured young they are easily tamed and prove most efficient agents in destroying rats, snakes, scorpions and other objectionable intruders. It was the small North Indian species that was, in 1872, introduced into Jamaica to combat the pest of rats which inflicted great damage on sugar cane plantations. The experiment proved eminently successful in reducing the numbers of the rats and was adopted by planters in adjoining islands. But the author does not mention the regrettable effect this introduction had upon the interesting avifauna of the islands, many of the ground-frequenting birds being virtually exterminated, while, it is said, the rats soon commenced to develop tree-nesting habits and so saved themselves from utter extermination from the mongooses, which are not good tree-climbers.

As a snake-killer the mongoose is greatly valued in India since it fearlessly attacks poisonous as well as non-poisonous kinds. It is not, we are told, immune to the effects of snake poison as has been asserted, but it almost invariably succeeds in evading the deadly fangs chiefly by its extreme activity in dodging the reptile's strokes. It is aided, too, by the long hairs of its body, which, during an encounter, are all erected, making its apparent bulk more than doubled, and it presents to the snake's aim a large area through which the fangs pass harmlessly.

The origin of the domestic dog has always been somewhat of a mystery though its affinity to the wolf has never been doubted. The author considers it a certainty that the wolf is the principal if not the sole ancestor, though admitting that the view that the jackal may have contributed to the strain cannot be dismissed, considering that some of the dogs possessed by Neolithic man were comparatively small. As the author remarks, "there is no mistaking the stamp of the wolf on such breeds as the Alsatian and the Eskimo", but it is difficult to imagine this ancestry in the case of the Pekingese or Griffon.

This book will long remain the standard work on the very rich mammalian fauna of the countries with which it deals. D. SETH-SMITH.

THE PRINCIPLE OF RELAXATION

Relaxation Methods in Engineering Science

A Treatise on Approximate Computation. By Prof. R. V. Southwell. (Oxford Engineering Science Series.) Pp. vii+252. (Oxford: Clarendon Press; London: Oxford University Press, 1940.) 17s. 6d. net.

THOSE who heard Prof. Southwell's lecture to the London Mathematical Society in 1937 will well remember how he communicated to his audience some of the great enthusiasm with which he had reacted to the method of relaxation, first advanced by Prof. Hardy Cross in 1932, and introduced to Great Britain by Prof. J. F. Baker, J. Morris and D. Williams (Aeronautical Research Committee, R. & M., 1667, 1670 and 1672). The great attraction of the method is that the engineering problem of estimating the stresses in a redundant steel framework is solved by a process of successive approximation, each step in which represents a definite engineering operation on the framework.

Imagine each joint fixed in position, and orientation by suitable jacks. As the prescribed loads are applied to the structure, the jacks are called upon to supply greater and greater constraining forces. Now ease off the jack carrying the greatest load, until it provides no constraint. The loads on the jacks holding the adjacent joints will change and so will the stresses in the adjacent members. Choose the jack which now carries the greatest load and ease *that* one off. It is evident that by this process we are approaching the condition in which no jack provides any constraint. Now Hardy Cross showed that the redistribution of loads and stresses due to slacking off one jack is easily calculable for an unbraced framework precisely because only adjacent joints and members are affected; and Morris and Southwell have extended his method to braced frameworks including members with end loads. We have therefore a method of successive approximation to the stresses in a given framework when no external forces constrain the joints. As Southwell said in his lecture, "You can describe this process in mathematical language, but when I talk about relaxation I can see the workmen at the jacks spitting on their hands".

The method of systematic relaxation, as developed and applied by Southwell, has become one of the most important methods of practical computation in modern engineering science. Its scope is by no means restricted to those problems of redundant structures in which it attained its first successes. In the hands of Southwell and of the school of research workers which he has established at Oxford, relaxation methods have been successfully applied to a bewildering variety of difficult and outstanding problems of plasticity, conformal transformation, vibrating systems, percolation and the like. Many of these applications are described in the present volume. Naturally, these advances have to be purchased at a price—that of careful and laborious computation according to the systematized process developed by Southwell—but, in the words of one of Southwell's students, "The method works if the computer is prepared to".

The present volume gives a masterly account of the applications of the relaxation method, and is invaluable for the engineer who is well acquainted with the mechanics of frameworks. But, if I may be allowed a personal criticism, I found it a difficult book to read. I think this difficulty arises because the reader is faced simultaneously with an entirely new method, and with somewhat specialized problems of stressing, vibrations, etc. What is really required is an introductory chapter explaining the essence of the relaxation method, a chapter which should be entirely abstract and mathematical and unencumbered by the details of practical problems.

The possibility of writing such an introduction arises from the fact that, to the eye of the mathematician, most of the early problems tackled by relaxation methods reduce in the last analysis to the solution of a set of linear simultaneous equations, while the practical difficulty of computation is due to the fact that the number of independent unknown variables is large, for example, a dozen or more.

Various methods of successive approximation have been devised for the solution of this type of problem, such as the powerful iteration methods due to Morris. Many (if not most methods) including the relaxation methods, require the system of linear equations to be "prepared" for computation by being reduced to the "normal" form. In this form the equations represent the conditions that a quadratic form in the unknowns should be an absolute minimum. This simple remark leads to a geometrical interpretation of the relaxation method, which is most easily visualized in the simplest case when there are only two unknowns.

The quadratic form to be minimized then represents the contour of a valley, the unknown variables being interpreted as latitude and longitude, and the numerical value of the quadratic form as height above sea-level. To minimize the quadratic form is to reach the lowest point in the valley in a thick mist, with no map, but having a compass. Southwell's relaxation method directs the lost explorer to walk downhill due north (or south) until the track he is following becomes momentarily level. Then to walk downhill due east (or west) until his track again becomes momentarily level; and thus to zig-zag down the valley sides until he is sufficiently near the absolute bottom part of the valley.

The method is delightfully simple and it suggests an obvious alternative. Instead of taking the direction of each walk to be due north or east, the explorer can take each walk in the direction of the line of steepest descent at the starting-point of each walk, and can continue the walk until the track he is pursuing becomes momentarily level. This procedure smooths out the zig-zags of the relaxation method; and for some time I thought that the method of steepest descent was an improvement upon the original relaxation method. A direct comparison of the two methods on the same problem soon showed, however, that the original relaxation method is much easier to apply and slightly more rapid.

An introduction on some such lines as these would, I think, be a great help to the novice—and most of us are novices when confronted with the type of problem discussed in this book. But, apart from this suggestion, the present work is above criticism, and Prof. Southwell has made us all his debtors by making his pioneer researches on relaxation methods available in such a convenient and delightful form. G. TEMPLE.

TORSIONAL VIBRATION PROBLEMS

Practical Solution of Torsional Vibration Problems
With Examples from Marine, Electrical, Aeronautical and Automobile Engineering Practice. By Dr. W. Ker Wilson. Second edition. Vol. 2. Pp. xxi+694. (London: Chapman and Hall, Ltd., 1941.) 42*s.* net.

THE objective treatment of the subject of torsional vibration which has been adopted by Dr. W. Ker Wilson leads inevitably to the call for more and yet more examples of the practical solution of problems such as arise in this increasingly important branch of the designer's work. The original single-volume treatise has now been enlarged to two very substantial volumes which greatly increase the scope of the work. This at the same time gives opportunity for the re-writing of sections such as that dealing with damping devices, which has been brought up to date and now includes a separate chapter on the rotating pendulum vibration absorber.

The second of the two volumes has recently been published, and the main feature of the presentation of the subject lies in the solution of problems met with in practice. It is, however, very far from being a fortuitous assortment of examples of this class of work, as there is a logical sequence of development of the subject. The volume opens with the determination of stresses due to torsional vibration at resonant speeds, and proceeds to the measurement of amplitudes, analysis of torsiograph records, damping and absorbing devices and dynamic characteristics of direct-coupled electrical generating sets.

There are some thirty worked examples which appear in their natural sequence in this order of treatment. The examples showing the harmonic analysis of vibration records, using 24 and 48 ordinates, provide a valuable guide to the solution of such problems when a mechanical analyser is not available. It may be confidently stated that Dr. Wilson's book will do much to simplify the application of vibration study to modern needs.

University Physics

By Dr. F. C. Champion. Part 3: Light. Pp. vii+172. 5*s.* 6*d.* net. Part 4: Wave-Motion and Sound. Pp. vii+67. 5*s.* net. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1941.)

THESE two books form part of a complete course in physics for university students. Both books are clearly and soundly written, and are excellently produced. There is a group of examples after each chapter, and at the end of each book there is a number of questions with answers and useful hints for solution.

"Light". In a book avowedly written for university students, and occupying only 172 pages, it is rather surprising to find space taken up with elementary work. Certain sections are marked with an asterisk indicating that Intermediate students may omit them, but not everybody will agree with Dr. Champion's selection of the parts to be omitted. The chapter on photometry is very good, though probably more information might have been given on photo-electric instruments, while the chapter on the emission and wave theories of light is excellent and makes one wish for more.

"Sound". In this book, which runs to only 57 pages of text, Dr. Champion starts with a treatment of wave motion and simple harmonic waves. This is an excellent beginning, but as one goes through the book one finds that in many cases just the basic information is given. This is probably the author's intention; nevertheless the students for whom the book has been written will require more.

Undoubtedly what Dr. Champion has given is excellent, but he has not given enough; a bibliography of reference books would probably have been helpful to students.

Mathematics for Engineers

By Raymond W. Dull. Second edition. Pp. xviii+780. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 35*s.*

THIS is the second edition of the author's treatise on mathematics designed for engineers. It was originally published in 1926 and the major change in this new issue lies in the addition of several new operations with the slide rule—which the writer calls the "engineer's assistant"—made possible by modern improvements in the design of that useful instrument. The course is intended to bridge the gap between the engineer's handbook and the purely mathematical text-book, the former being too concise and incomplete, while the latter is too specialized. Considerable space is assigned to the treatment of error—absolute and relative—and to practical use of the slide rule.

The artificial boundaries between the various branches of the subject are commendably swept aside and, between the simple arithmetic of the first chapter and the multiple integration of the last, there is, in the intervening fifty-five chapters, a comprehensive and practical review of algebra, pure and analytical geometry, mensuration, trigonometry, ncluding complex numbers, and calculus. The text s well illustrated by worked examples and clearly drawn diagrams. A few minor misprints are noticeable in which the phrase, "knots per hour", may be be included. As a review and work of reference, the book should be quite useful to those for whom t was written.

F. G. W. B.

The Foundations of Geometry

By Prof. Gilbert de B. Robinson. (Mathematical Expositions, No. 1.) Pp. xi+167. (Toronto: University of Toronto Press, 1940.) 2 dollars.

THERE are several excellent treatises dealing exhaustively with modern ideas of geometry and analysis, but the bulk and difficulty of these works repel those who are not specialists. The University of Toronto is publishing a series of "Mathematical Expositions", which will present topics in a readable fashion, with particular attention to showing how modern theories of mathematics arise naturally from considerations well known to elementary students. The first volume, Prof. Robinson's "The Foundations of Geometry", carries out this programme so far as it concerns the more usual kinds of geometry, leaving non-Euclidean geometry to be dealt with in a later volume. Part I considers the axiomatic foundation of projective geometry and of Euclidean geometry, and shows the relation between these. Part II deals with the more difficult questions of number, order and continuity. Those with a good knowledge of school geometry should find the book very helpful as a bridge between the old domains and the new.

Future volumes in this series will include "The Infinite in Mathematics" and "The Theory of Interest".

Opera hactenus inedita Rogeri Baconi

Fasc. 16: Communia Mathematica Fratris Rogeri. Partes prima et seconda. Nunc primum edidit Dr. Robert Steele. Pp. xii+162. (Oxford: Clarendon Press; London: Oxford University Press, 1940.) 15*s.* net.

ROGER BACON (1214–1294) produced in 1267 his four-volume Latin encyclopædic treatise ("Opus Majus") on the foundations of knowledge, with two supplements dealing with physical science and mathematics. The "Communia Mathematica" appears to be an amplified version of the second supplement, assembled from various manuscripts by someone unknown, probably about 1428. For the modern reader the interest of the work is mainly in showing what mathematical literature and teaching were available at the time, and what Bacon thought of the teaching of Boethius, who moulded scientific thought of the early Middle Ages until the complete acceptance of Aristotle's physics. The first part of the "Communia" deals with the relation of mathematics to other branches of learning. The second part considers certain parts of mathematics in detail, particularly the theory of proportion. The criticism of some of Euclid's assumptions and definitions shows that Bacon was far in advance of this time. As is well known, he was accused of magic and condemned to imprisonment for life.

Differential Equations

By G. S. Diwan and Prof. D. S. Agashe. Pp. x+316. (Bombay: Prof. D. S. Agashe, St. Xavier's College, 1941.) n.p.

THIS book, intended for a first degree course in Indian universities, gives a rather detailed account of the usual devices for obtaining a compact solution of differential equations designed to yield to the appropriate device. For this purpose it may be found useful.

L. M. M.-T.

MECHANISM AND CHEMICAL KINETICS OF ORGANIC REACTIONS IN LIQUID SYSTEMS*

By DR. E. D. HUGHES
University College, London

THE theory of chemical kinetics owes much of its development to the ease with which organic reactions lend themselves to convenient measurement, but the debt has been amply repaid, for kinetic studies have contributed very materially to the elucidation of the mechanism of organic processes. The importance of the kinetic method in the study of mechanism was demonstrated many years ago, particularly by Lapworth, Orton and others in the early years of the present century. More recently, it has been given enhanced value by the important advances in the physical interpretation of kinetic data (especially in liquid systems), and it has played a notable part in the rapid development which the theory of organic reactions has undergone since the enunciation of the electronic theory of valency. Of the conclusions derived from investigations in this field in the last decade, one of the most important, and one which is widely illustrated in this discussion, is that a reaction may follow different mechanisms in not very drastically altered circumstances. This fact emphasizes still further the importance of kinetic control in the study of reactions. With the aid of kinetics, chemical behaviour can be related to mechanism and its determining factors, chemical structure and physical conditions, and the solution of outstanding problems can thus be greatly facilitated.

The reactions which come under review involve three main processes which are quite closely related, namely, substitution, elimination and addition. The substitution reactions may be divided into three principal types, as illustrated in the following table (the dots in the formulæ representing electrons)[1]:

TYPES OF SUBSTITUTION.

(*A*) **Heterolytic**

(1) Nucleophilic

$$Y : + R \,|\, . . X \rightarrow Y{-}R + : X \;.\;.\;.\;.\; (S_N).$$

(example : $H\bar{O} + R{-}Cl \rightarrow HO{-}R + \bar{Cl}$)

(2) Electrophilic

$$Y + R \;.\;.\, | X \rightarrow Y{-}R + X \;.\;.\;.\;.\; (S_E).$$

(example : $\overset{+}{D} + R{-}H \rightarrow D{-}R + \overset{+}{H}$)

(*B*) **Homolytic**

$$Y . + R . | . X \rightarrow Y{-}R + . X$$

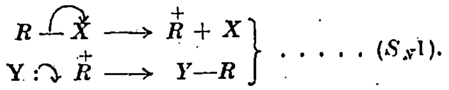
(example : $D + H{-}H \rightarrow D{-}H + H$).

The mechanism of reactions related to the first of these types will now be discussed; reactions of the second and third type are considered in the sequel.

In a simple nucleophilic substitution[1], of the form $Y + R{-}X \rightarrow Y{-}R + X$, the nucleophilic reagent Y, whatever its original charge, must become one unit more positive; and the expelled group X one unit more negative; Y may therefore be either negative or neutral (for example, $\bar{I}$, $\bar{O}H$, NR_3, SR_2, etc.), and X either formally neutral or positive (for example, Cl, $\overset{+}{N}R_3$, $\overset{+}{S}R_2$, etc.). The kinetics of these reactions call for the recognition of two distinct mechanisms. The first is a one-stage process, which is termed 'bimolecular' because two molecules are undergoing covalency change:

$$Y : \curvearrowright R \!-\! \ddot{X} \longrightarrow Y - R + \ddot{X} \;.\;.\;.\;.\;.\; (S_N2).$$

(In this formulation, and elsewhere in this article, arrows are used to show the direction of electron displacements; sign labels on X and Y have been omitted because of the various possibilities already mentioned.) The second mechanism is a two-stage process, wherein a rate-determining ionization is succeeded by a reaction between the formed carbonium ion and the substituting agent:



$$\left.\begin{array}{l} R - \ddot{X} \longrightarrow \overset{+}{R} + X \\ Y : \curvearrowright \overset{+}{R} \longrightarrow Y{-}R \end{array}\right\} \;.\;.\;.\;.\;.\; (S_N1).$$

This mechanism is termed 'unimolecular', because only one molecule ($R{-}X$) is undergoing covalency change in the rate-determining stage. The unimolecular mechanism is favoured relatively to the bimolecular mechanism by the following principal factors: (1) low nucleophilic activity in the reagent Y, (2) large electron-release from the group R, (3) strong electron-affinity in the group X, (4) high ionizing capacity in the solvent. It may also be added that the unimolecular mechanism is less sensitive to steric inhibition by substituent groups than is the bimolecular mechanism. When the reaction centre is asymmetric, the bimolecular mechanism invariably leads to inversion of configuration, while the unimolecular mechanism may give rise, depending on structural influences, either to retention of configuration or to racemization with predominating inversion.

For certain simple substitutions of the type now considered, Polanyi and others have calculated the activation energies to be expected on the basis of the above mechanisms. The values thus deduced are in reasonably good agreement with the experimental results. In the case of the 'symmetrical' halogen-exchange reactions (bimolecular), for example, $\bar{Cl} + CH_3.Cl \rightarrow Cl.CH_3 + \bar{Cl}$, a very simple method of calculation has now been described[2]. In first approximation, the activation energy is taken as the energy necessary to extend the carbon – halogen bond until it has the length corresponding to a carbon atom and a halide ion in contact, and it is shown that the introduction of various refinements into this procedure does not materially affect the result.

The same fundamental mechanisms operate in aromatic side-chain substitution[3], but interesting differences of behaviour are sometimes observed when the polar effects of certain substituents in the nucleus are compared with the effects of the same substituents when attached to a saturated system. With alkyl groups, for example, the predominating influence with respect to a reaction in a saturated system such as the replacement of halogen in an organic halide, $R—CR'_2—Br$, by the usual mechanisms (S_N1 and S_N2), is the general 'inductive' effect, which increases from left to right in the series, $R = CH_3$, $CH_3.CH_2$, $(CH_3)_2CH$, $(CH_3)_3C$; thus $CH_3 \rightarrow CH_2 \rightarrow CR'_2 \rightarrow Br > CH_3 \rightarrow CR'_2 \rightarrow Br$. When the unsaturated aromatic nucleus is interposed between the alkyl group and the reaction centre, however, another effect gains in importance and occasionally becomes the dominant influence; this is the 'electromeric' effect, which arises from suitably placed C—H bonds and decreases as the operative hydrogen atoms are replaced; for example:

---

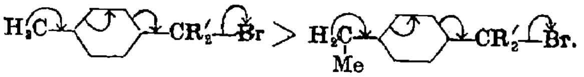
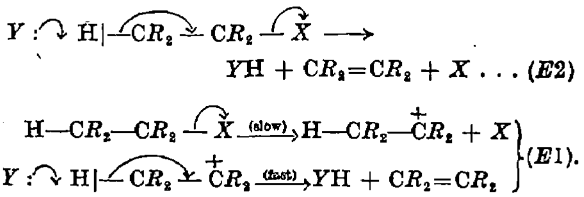
A full discussion of the various topics, with literature citations, is contained in these papers.



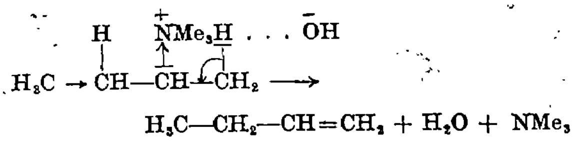
Substitution and elimination occur together so often as to suggest that the duality of mechanism established for substitution might have a parallel in the mechanism of elimination. This is found to be the case[4]. Employing the nomenclature and schematic representation already explained in connexion with nucleophilic substitution, the bimolecular ($E2$) and unimolecular ($E1$) mechanisms of elimination may be illustrated as follows ($Y = \bar{O}H$, $\bar{O}Ac$, NR_3, H_2O, etc.; $.X = .\text{Hal}$, $.SO_2R$, $.\overset{+}{S}R_2$, $.\overset{+}{N}R_3$, etc.):



$$Y: H|—CR_2—CR_2—X \longrightarrow YH + CR_2{=}CR_2 + X \ldots (E2)$$

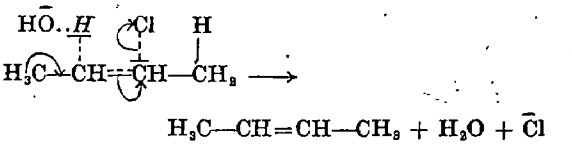
$$\left.\begin{array}{l} H—CR_2—CR_2—X \xrightarrow{\text{(slow)}} H—CR_2—\overset{+}{C}R_2 + X \\ Y: H|—CR_2—\overset{+}{C}R_2 \xrightarrow{\text{(fast)}} YH + CR_2{=}CR_2 \end{array}\right\}(E1).$$

With the recognition of these mechanisms, and with full appreciation of their relationship with the substitution processes, the apparently inconsistent observations of the older literature fall into place, and it is possible to make rationally based predictions as to the effect of chemical constitution and physical conditions on the phenomenon. Special interest is attached to the analysis of the factors governing the contrary tendencies implied in two well-known empirical rules, namely, the Hofmann and Saytzeff rules, which indicate the preferred direction of olefin elimination in alkyl 'onium salts and in branched-chain alkyl halides respectively. (The Hofmann rule refers to the preferential formation of that ethylene which bears the smallest number of alkyl groups; Saytzeff's rule, on the other hand, predicts the production of the most alkylated of the possible alkyl ethylenes.) It is found that bimolecular 'onium salt reactions are subject to the Hofmann rule, while the bimolecular reactions of halides, and the unimolecular reactions of both 'onium salts and halides, are governed by the Saytzeff rule. Furthermore, the Hofmann and Saytzeff influences are shown to be manifestations of the operation of the inductive and electromeric effects, respectively, of alkyl groups (compare preceding paragraph); for example:



$$H_3C—CH_2—CH{=}CH_2 + H_2O + NMe_3$$

The inductive effect of the β-methyl group *inhibits* the removal of a β-proton (Hofmann influences).



$$H_3C—CH{=}CH—CH_3 + H_2O + \bar{Cl}$$

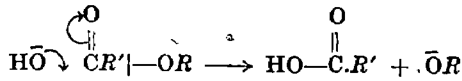
The electromeric effect of the β-methyl group *facilitates* the removal of a β-proton (Saytzeff influences).

The theory of aliphatic substitution can also be applied to the problem of carboxylic esterification and hydrolysis[5]. In this instance, it is necessary, in the first place, to distinguish between 'basic' reactions (hydrolysis in neutral or alkaline solutions) and 'acidic' reactions (acid-catalysed hydrolysis and esterification). In the former the carboxylic entity which suffers reaction is $R'.CO_2R$, while in the latter it is $[R'.CO_2HR]^+$. (In general, hydrolysis and esterification may be treated similarly; in esterification ($R = H$), however, the basic reaction is suppressed.) Secondly, there are two distinct modes of bond-fission, namely, 'acyl-oxygen fission' and 'alkyl-oxygen fission'; and, in both basic and acidic reactions, either the one or the other may take place according to circumstances. There are thus four main types of reactions, which, with respect to the carboxylic entity and its mode of fission, may be represented:

	Basic Reactions	Acidic Reactions
Acyl-oxygen fission:	$R'.CO|—O—R$	$[R'.CO|—OH—R]^+$
Alkyl-oxygen fission:	$R'.CO—O—|R$	$[R'.CO—OH—|R]^+$

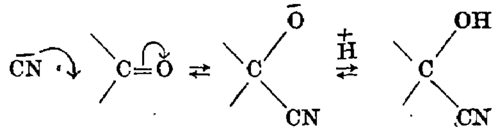
In esterification ($R = H$), there is a corresponding fission in the alcohol, that is, $R—O—|H$ (in acyl-oxygen fission) and $R|—O—H$ (in alkyl-oxygen fission). Finally, it would appear, from the rather limited amount of suitable kinetic data, that, for certain of these reactions, two mechanisms exist which are related to each other just like the unimolecular and bimolecular mechanisms of simple nucleophilic substitution.

As in certain of the reactions involved in carboxylic esterification and hydrolysis, for example,

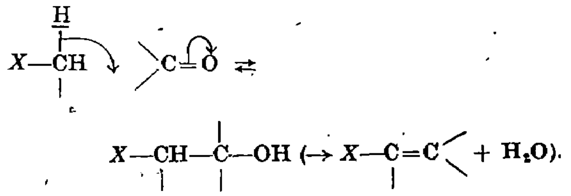


$$H\bar{O}\ \overset{O}{\overset{\|}{C}}R'|—OR \longrightarrow HO—\overset{O}{\overset{\|}{C}}.R' + .\bar{O}R,$$

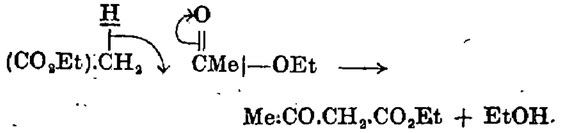
the addition and condensation reactions of carbonyl compounds[6] are dependent on the reactivity, towards nucleophilic reagents, of the carbon atom of the carbonyl group. A simple example is to be found in cyanohydrin formation, the mechanism of which was clearly indicated by Lapworth's classical kinetic investigations:



while reactions of the Aldol, Claisen, Knoevenagel and Perkin type follow a similar, though somewhat more complex, plan, for example:

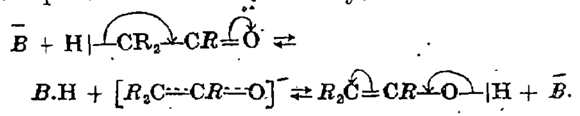


The Michael and the Thorpe reactions typify a quite analogous addition of a nucleophilic reagent to suitably activated C=C and C≡N bonds respectively.) All these reactions have certain features in common; thus they generally exhibit both alkaline and acid catalysis, and, while one of the reactants is a carbonyl compound, the second component contains a labile hydrogen atom which is activated by at least one electron-attracting substituent (*X*). The function of the basic catalyst is to remove the proton, thereby creating a more powerful nucleophilic reagent, and there is kinetic evidence that this reaction may, in certain cases, constitute the rate-determining stage of the process. An acid catalyst, on the other hand, probably activates the carbonyl component by forming an oxonium complex, $>\text{C}=\overset{+}{\text{O}}\text{H}$. Reactions of the type of the acetoacetic ester condensation are also similar, and the analogy with the alkaline hydrolysis of esters is even more striking in this case:



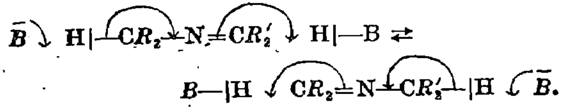
$$(\text{CO}_2\text{Et}).\text{CH}_2\text{—H}\ \ \text{CMe}(=\text{O})|\text{—OEt} \longrightarrow \text{Me.CO.CH}_2\text{.CO}_2\text{Et} + \text{EtOH}.$$

The protropic changes of carbonyl compounds[7], like the reactions discussed in the preceding paragraph, are catalysed both by bases and by acids. In terms of the ionic theory of prototropy, this circumstance is easily explained, for, according to this theory, the change involves the removal of a proton and the addition of a proton, processes which will obviously be facilitated by bases and by acids respectively. In the base-catalysed reaction, it is generally accepted that the first step involves the transfer of a proton to the catalyst, a 'mesomeric' anion being produced, which, by accepting a proton (for example, from the medium or the conjugate acid of the base), can form either the one or the other component of the tautomeric system:



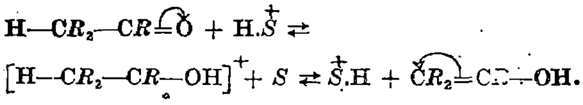
$$\bar{B} + \text{H}|\text{—CR}_2\text{—C}R=\text{O} \rightleftharpoons B\text{.H} + [R_2\text{C}\cdots\text{C}R\cdots\text{O}]^- \rightleftharpoons R_2\text{C}=\text{C}R\text{—O—}|\text{H} + \bar{B}.$$

The equality of the rates of halogenation, of protium-deuterium exchange and of racemization, which has been demonstrated for certain ketones (asymmetric at the α-carbon atom), thus receives a simple interpretation if it be assumed that the rate-determining stage in all these reactions is the formation of the mesomeric anion. Similar ideas can be applied to other prototropic systems, but in certain cases (for example, methyleneazomethines) there is evidence that the anion never attains kinetic freedom, the removal of one proton and the addition of another being simultaneous:



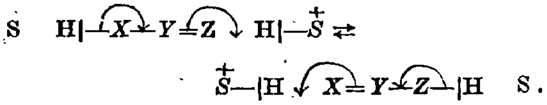
$$\bar{B}\ \text{H}|\text{—C}R_2\text{—N}=\text{C}R'_2\ \ \text{H}|\text{—B} \rightleftharpoons B\text{—}|\text{H}\ \ \text{C}R_2=\text{N—C}R'_2\text{—}|\text{H}\ \ \bar{B}.$$

In acid catalysis, the preliminary addition of a proton to the tautomeric system may facilitate the subsequent transfer of another proton from the latter to the solvent (*S*):



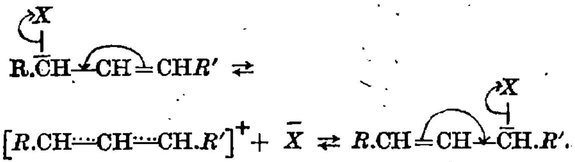
$$\text{H—C}R_2\text{—C}R=\text{O} + \text{H.}\overset{+}{S} \rightleftharpoons [\text{H—C}R_2\text{—C}R\text{—OH}]^+ + S \rightleftharpoons \overset{+}{S}\text{.H} + \text{C}R_2=\text{C}R\text{—OH}.$$

Alternatively, the proton addition and eliminatio may take place simultaneously:



$$S\ \ \text{H}|\text{—}X\text{—}Y=Z\ \ \text{H}|\text{—}\overset{+}{S} \rightleftharpoons \overset{+}{S}\text{—}|\text{H}\ \ X=Y\text{—}Z\text{—}|\text{H}\ \ S.$$

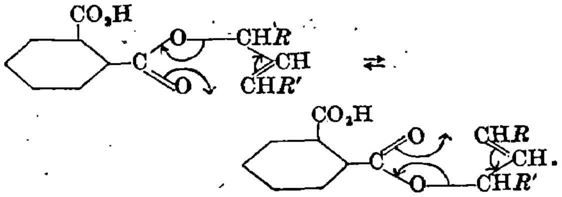
Anionotropic change[8] is, in some respects, simila to prototropic change, and it is also related t nucleophilic substitution. In anionotropy we ar concerned with the movement of negative groups and there is evidence that the interconversion ma proceed through the intermediate formation of positive mesomeric ion and a complementary negative ion; for example,



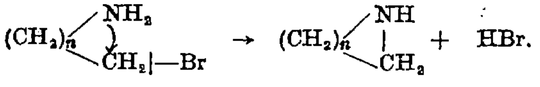
$$R\text{.CH}X\text{—CH}=\text{CH}R' \rightleftharpoons [R\text{.CH}\cdots\text{CH}\cdots\text{CH.}R']^+ + \bar{X} \rightleftharpoons R\text{.CH}=\text{CH—CH}X\text{.}R'.$$

(. *X* = . Hal., . OH, . O*R*, . O.CO.*R*, etc.)

It has been shown that the mobility of the syste is increased by the following factors: (1) Stron electron-affinity in the group *X*, (2) large electron release from the group *R*, (3) high ionizing capacit in the medium. These are the relationships to b expected if ionization is involved, and it will b recalled that the same factors assist the ionizatio mechanism of nucleophilic substitution (S_N1). Al the facts relating to the phenomenon cannot, however, be explained on the basis of this mechanism alone. It has been shown, for example, that th anionotropic rearrangement of optically active hydrogen phthalates of substituted allyl alcohols is ofte accompanied by a high degree of retention of optica activity, and an intramolecular mechanism has bee suggested to account for this and similar observations



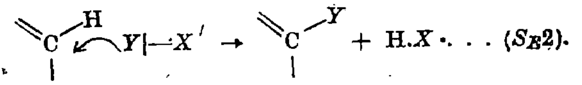
In the study of the kinetics and mechanism o ring-closure[9], the reactions which have yielded th most profitable results are mainly those which involv an internal nucleophilic substitution; for example



$$(\text{CH}_2)_n{<}^{\text{NH}_2}_{\text{CH}_2|\text{—Br}} \rightarrow (\text{CH}_2)_n{<}^{\text{NH}}_{\text{CH}_2} + \text{HBr}.$$

Since the intermolecular processes which generall accompany the cyclization involve two such molecules, and are therefore of a higher order, the bes yields of cyclic derivatives are obtained in dilut solutions. This principle has been widely exploite both in synthetic work and in the simplification o kinetic experiments. The most important aspect o this subject concerns the effect of homology, and c the notable results which have been obtained in thi connexion perhaps the most interesting relate to th great ease of formation of three- and five- (but no four-) membered rings, the special difficulty of forming rings of about nine to eleven atoms, and th alternation between odd- and even-numbered structures which is clearly exhibited in the higher members. The factors responsible for these effects are obviously rather complex, but the two most important are probably the 'distance' and 'strain' factors of Ruzicka's well-known theory, the former assisting the cyclization of short chains, and the latter favouring the formation of strainless rings.

In the replacement of hydrogen in the aromatic nucleus[10], we have a clear example of electrophilic substitution, and, since the attack of the reagent is an essential condition for the expulsion of the displaced atom (mechanism S_E2), the reaction rate will depend primarily on the electrophilic activity of the reagent and the electron availability at the reaction centre :



Concerning the reagent, it has been suggested that the efficacy of a halogenating or nitrating agent, $X.Y$ (Y = Hal. or NO_2), increases with the electron affinity of X (as indicated, for example, by the acid-strength of $H.X$) ; for example, Cl.Br > Br.Br > HO.Br ; $SO_4H.NO_2(a) > H_2\overset{+}{O}.NO_2(b) > AcO.NO_2(c) > HO.NO_2(d) > \bar{O}.NO_2(e)$. The predicted sequence of brominating agents has been confirmed experimentally, and the order with respect to nitration is consistent with the assumption that the reagents mentioned are effective when the reaction is carried out in sulphuric acid (a), sulphuric acid or fuming nitric acid (b), acetic anhydride (c), acetic acid (or similar inert solvent) (d), and water (e).

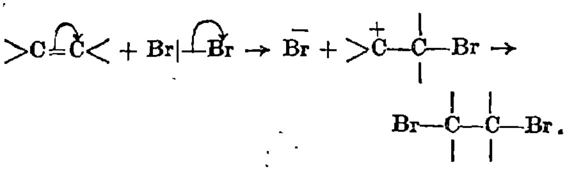
A consideration of the second factor, namely, the electron availability at the reaction centre, must take into account the 'directing' influence of a substituent group with respect to further substitution. Numerous experimental investigations and theoretical arguments concerning this problem have led to a conclusion which may be broadly summarized in the following statement : Electron-releasing groups (for example, $.CH_3$) or electron-attracting groups (for example, $.NO_2$, $.CO_2Et$) increase or decrease, respectively, the electron availability (and, consequently, the reactivity towards the electrophilic reagent) in all the nuclear positions, but more so in the o- and p-positions than in the m-position, the former groups therefore leading to a predominating o,p-substitution and the latter to m-substitution. This is well illustrated by the relative partial rates of nitration, for the various positions in benzene, toluene and ethyl benzoate, tabulated below :

	Ortho	Meta	Para
$C_6H_5.H$	1	1	1
$C_6H_5.CH_3$	43	3·0	55
$C_6H_5.CO_2Et$	0·0026	0·0079	0·0009

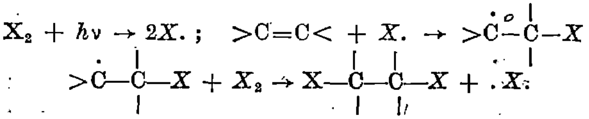
(These 'partial rate factors' are obtained by combining the figures for the total rates of nitration of the mono-substituted compounds relative to benzene (determined by a 'competition' method) with the proportions of isomerides formed.) In the chlorination of certain phenolic ethers, it has been shown that the effects of substituent groups on the reaction rate are reflected in approximately equivalent changes in the Arrhenius critical energies, and this important result has since been observed for several other reactions.

General experience relating to the effect of nuclear substituents on the Friedel-Crafts reaction[11] supports the view that it may be regarded as another example of the type of substitution discussed in the preceding paragraph. (Compare, for example, the inhibitory effect of nitro-groups ; and the difficulty of avoiding polyalkylation during attempted monoalkylation (activation by alkyl substituents), contrasted with the fact that no similar difficulty attends monoacylation (deactivation by acyl substituents). Apparent anomalies in the orientation of the substitution can be satisfactorily explained on the basis of the interconversion of products which is known to occur in the presence of the metal halide catalysts. The formation of abnormal proportions of m-derivatives in the alkylation of alkyl benzenes, for example, illustrates the tendency to form the product in which the activation of one alkyl group by the other is least, that is, the most stable isomer.) The most interesting aspect of the reaction concerns the effect of the catalysts employed, of which the most common are the halides of boron, aluminium and iron. It is now widely accepted that the most important function of the catalyst is to increase the electrophilic activity of the substituting agent by the conversion, through complex formation, of a mainly covalent carbon-halogen bond into one of essentially ionic character : $R:\ddot{Cl}:\curvearrowright AlCl_3 \rightarrow R^+[AlCl_4]^-$. Substantial evidence in favour of this interpretation has been obtained by conductivity, dielectric polarizability, and radio-isotopic exchange measurements in solutions containing the organic and inorganic halides. The electron deficiency in the alkyl component of the complex should favour the formation of secondary rather than primary, and tertiary rather than secondary, derivatives, thus accounting for the rearrangement of the alkyl group which is frequently encountered in the Friedel-Crafts reaction.

Addition to olefinic compounds[12] is related to electrophilic substitution, for, in the normal course of events, the reaction is initiated by the attack of an electrophilic reagent on the unsaturated carbon atom at which the electron density is highest. In the thermal addition of halogen in certain dissociating solvents, for example, it is well established that the following two-stage mechanism is involved :



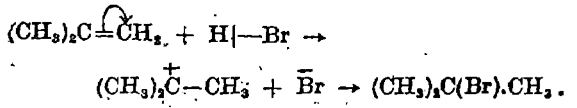
Evidence in favour of this mechanism is afforded by the effect of substituents of known polar character on the reaction rate, by the intervention of extraneous anions or a reactive solvent in the second stage of reaction (for example, bromohydrin formation in aqueous solution), and by the stereochemical data. It may be expected to function in its simplest form in dissociating solvents only, and this is confirmed by the experimental results. In non-dissociating solvents, and in the gas phase, the thermal halogenation is highly sensitive to the presence of stray catalysts, and a heterogeneous reaction involving the walls of the containing vessel often intervenes. Under these conditions the reaction is obviously very complex, and some of the observations may even indicate an atomic mechanism. The gaseous photo-addition undoubtedly involves neutral atoms and free radicals (*cf.* following paragraph), and this may also be true of the corresponding reaction in solution :



$$X_2 + h\nu \rightarrow 2X. ;\quad >C{=}C< + X. \rightarrow >\dot{C}-\overset{|}{\underset{|}{C}}-X$$

$$>\dot{C}-\overset{|}{\underset{|}{C}}-X + X_2 \rightarrow X-\overset{|}{\underset{|}{C}}-\overset{|}{\underset{|}{C}}-X + .X$$

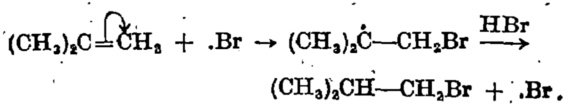
Homolytic reactions involving free radicals[13] (compare Table of Types of Substitution) exhibit some similarity to the heterolytic processes in which electrophilic reagents are concerned, because free radicals generally have depleted electron shells and tend to share an extra electron: for example, $C_6H_5. + Cl-CCl_3 \rightarrow C_6H_5-Cl + .CCl_3$. Their electrophilic character is most clearly shown in the addition reactions with olefins. In the so-called 'normal' addition of hydrogen bromide to the alkylethylenes, the proton adds preferentially to the unsaturated carbon atom bearing the smaller number of alkyl groups (cf. Markownicoff's rule), for example,



$$(CH_3)_2C{=}CH_2 + H|{-}Br \rightarrow$$

$$(CH_3)_2\overset{+}{C}-CH_3 + \overset{-}{Br} \rightarrow (CH_3)_2C(Br).CH_3 .$$

Likewise, in the peroxide-catalysed reaction ('abnormal' addition), *the addition is initiated* by the attack of a bromine atom at the point of higher electron density :



$$(CH_3)_2C{=}CH_2 + .Br \rightarrow (CH_3)_2\dot{C}-CH_2Br \xrightarrow{HBr}$$

$$(CH_3)_2CH-CH_2Br + .Br.$$

It must be emphasized, however, *that this* analogy between neutral radicals and electrophilic reagents has definite limitations. Thus, it is well known that aromatic substitution reactions of neutral radicals, for example, $Ph. + H.C_6H_4R \rightarrow Ph.C_6H_4R + .H$, do *not exhibit the usual orientation effects* associated with the heterolytic reaction. This is understandable, for the 'orienting' influence of a substituent group is due to its transmitted polar effects, which are largely dependent on the demands of the reaction *involved, and it is reasonable to suppose that the* electron displacements which are a necessary condition for an oriented heterolysis are of less importance in homolysis.

It has been shown that the Cannizzaro reaction[14] exhibits peroxide catalysis and other characteristics of a radical process, and the observations can be satisfactorily accounted for on the basis of a mechanism involving the radicals RCO and $RCHOH$, both of which are formed from the aldehyde $RCHO$ by univalent oxidation and reduction respectively.

USE OF SCIENCE AND SCIENTIFIC WORKERS IN THE WAR

THE sessions during the morning and afternoon of the last day of the Conference organized by the Association of Scientific Workers and held in London during January 10–11 dealt with the two related topics: the utilization of scientific personnel, and the application of scientific knowledge to production and Services problems.

After an introductory address by Prof. S. Chapman, in which he compared the use of science in the War of 1914–18 and in this War, Prof. W. Wardlaw spoke on the working of the Central Register. He stated that the Register has come in for a good deal of criticism but that it should be borne in mind that nearly all the persons enrolled on the Register are already in useful work from which they can only move to more important posts. The Register is intended to be a complete record of the higher administrative, professional and technically qualified personnel of Great Britain, whether employed or not. The number of engineers and scientific workers on the Register has risen from 65,000, in May 1940, to 167,000, in December 1941. It has never been the function of the Register to determine how scientific and technical knowledge should best be used in the prosecution of the War; its purpose is to meet demands for technical personnel for war purposes and to allocate the available supply in cases of scarcity. He pointed out that technical officers of full professional standing are now at the head of each section, and referred to the formation of the Technical Personnel Committee under the leadership of Lord Hankey.

Prof. Wardlaw then dealt with the new procedure of progressive de-reservation being conducted by the District Manpower Boards of the Ministry of Labour. He stated that steps are being taken to ensure that anyone with technical qualifications of Central Register standard, if not already deferred by virtue of his work, will be dealt with by the Register and placed in work which makes full use of his technical capacity, whether in the Forces or not.

Mr. E. D. Swann, of the executive committee on the Association of Scientific Workers, presented the results of inquiries by the Association into the position in the main industries in the country. It has been found that many scientific workers and engineers are not being used on war work but are engaged instead on development and design for the period of post-war competition. Others who are nominally engaged on war work have insufficient to occupy their time fully. He stated that the Essentia Works Order is being used to hold redundant staff that no mechanism exists for providing partly occupied laboratories with *further problems*, and that there is considerable duplication of work in laboratories and design departments of similar undertakings. He pointed out the need for provision for the proper pooling of information, including trade secrets. Another weakness is the notable lack of contact between the design departments of the Ministries and the design and production departments in industry. It has been found that criticism of designs from the point of view of speed and economy of manufacture is not encouraged. The Association has collected enough evidence of thi sort to press for an investigation into the utilization of our technical resources by the Select Committe on National Expenditure.

Mr. Swann then dealt with the Association's proposal that a Technical Planning Committee should be set up under the Production Executive. This Committee would deal with the technical resource of Great Britain in the same manner as the existing Industrial Capacity and Materials Committees deal with their respective resources. In this scheme it is essential that this Committee be given executiv powers. The *Association of Scientific Workers*, as i is composed of working men of science and technicians is in a position to know how effective is the present organization in practice, and it knows that it is not working satisfactorily. Central planning of scientific work is essential, and scientific committees must have contact with working men of science on the job.

The position inside the Services was considered by two speakers at some length. Prof. H. Levy stressed the vital importance of having trained men of science inside the Armed Forces. He wants to see scientific men actually at the front who could bring back all kinds of relevant information of a technical nature. He pointed out that in Great Britain scientific education is not considered in selecting personnel for the higher commands. He stressed that not only military men should be chosen, but also scientific men who have had knowledge and experience of military matters.

Mr. F. Morgan, an operational research scientist attached to an R.A.F. command, provided a first-hand review of this type of work. He described how a number of workers are drafted from research to battle centres to ensure that the best use is made of their inventions. Now these men have acquired an operational outlook and can tell their research establishment what the Command most needs; that is, they can initiate research on new equipment and suggest modification to existing equipment. But their most useful function lies in helping Command to make the best use of equipment provided. This involves education of the people who use it, statistical analysis of the ways in which it can be used, and general investigation and the arrangement of tests. He pointed out in the second connexion that his Command now analyses everything numerically from efficiency of weapons to comparison of tactics. As a result, scientific workers are able to suggest and invent manœuvres—they are no longer "amateur strategists".

Mr. Morgan emphasized the importance of methods of communication in this War, and stated that automatic equipment has not been exploited as it should. He illustrated how in the problem of night fighting, mathematicians, physicists, biochemists, psychologists and physiologists are all needed. He hopes that there will be a permanent place in the Services for such scientific field work, and suggested the formation of a central research body for all the Services, and a greater measure of inter-Service liaison. It was significant that he pointed out from the other side the tenuous connexion between operational and industrial scientific workers. Further, he asked for closer contact with their colleagues in all Allied countries. His was a thoughtful paper which made a deep impression on the Conference. In pointing out the not inconsiderable risks which this type of work involves, he expressed the grievance that there is no special compensation for dependants in the event of casualties sustained on flying duties and that promotion is slow relative to the Service rate.

A most refreshing contribution was that of Mr. T. Halse, of the Industrial Committee of the Association. After citing several of the more extreme instances where the present lack of planning has led to marked inefficiency, he dealt with the ways in which the scientific worker in industry could help better the situation. Most important of these is participation in Production Committees, whether actually in the factory or regionally. He underlined the need for the scientific workers themselves to be organized to get the best results in this direction.

There were numerous papers in which were instanced in detail and from first-hand experience bad examples of misuse or inefficient utilization of technical knowledge. Mr. R. E. Foster reported that in his laboratory, which is attached to a large aero-engine factory, most of the work consists in rechecking materials which have already been subjected to Air Ministry inspection and release. There is also a considerable amount of slack time in his laboratory, although members have been refused their release on the grounds of pressure of work. When dealing with the position in the research department of this firm he mentioned that there is insufficient allocation of funds for new equipment, lack of space, and inadequate pay for the research staff. He and his colleagues believe that production is being severely handicapped by lack of scientific planning and management, and by lack of co-operation between management and staff, and between staff workers and manual workers. Continuing, he suggested remedies, emphasizing the part of Production Committees, and calling for the national pooling of all resources of development and research and full interchange of all experimental and production data, regardless of vested interests.

The present situation in the chemical industry was considered by Mr. A. Dooley. Whereas the engineering industry is mainly based on mass-production methods, the chemical industry demands the existence of *teams* of workers, embracing manual, scientific and clerical workers. There should be no arbitrary breaking up and re-assembling of such groups, and replacement personnel should be specially trained to maintain the efficiency of the group as a whole. We can expect that the extension of the War will create a demand for substitute products and the reclamation of used material on a large scale. This will bring into active war production sections of the chemical industry which have been kept more or less in reserve.

Mr. Dooley dealt especially with the rubber situation. At the moment, in Great Britain, we reclaim only one fifth of the proportion reclaimed in the United States, and an American authority has estimated that it would take 18–24 months to construct new plants. Our capacity for synthetic replacement manufacture appears to be negligible, but we could draw on the extensive experience of the United States and the U.S.S.R. Dove-tailed planning would be necessary, and electric power on a large scale may be essential. With regard to the technical development of substitute and reclaimed material, it is important to ensure close collaboration between the Services, rubber users, research associations and the chemical industry, and this applies also to resins and textile substitutes. The problem is on too large a scale for it to be carried through effectively by haphazard methods.

A notable set of contributions were those which dealt with the protection of the health of the industrial worker. Dr. T. O. Garland in a forceful speech directed attention to the comparative indifference with which many managements have treated this question in peace-time. Recently the British Medical Association has issued a report which advocates medical supervision of workers in every factory, large or small, which should aim at reducing the general sickness rate as well as the accident rate. Dr. Haden Guest has stated that the number of medical men in industry is a very small proportion of those in the Services. Dr. Garland asked for medical men to be called up into industry as well as into the Forces. With the building of large munition factories the situation is aggravated, because the general practitioner service is not sufficient to cope with this extra work. Dr. R. O. Stanford supported this suggestion, quoting from his own experience as a medical officer at a large factory. He sketched a plan for mass-radiography of workers in order to diagnose the early stages of tuberculosis, a disease which is on the increase. Dr. D. McClean, of the Lister Institute, stressed in this connexion that all milk sold to the public should be *safe* (that is, not infected) milk.

The Oxford vaporizer, a simple apparatus for administering anæsthetics under battle conditions, was described by Dr. K. Mendelssohn, of the Clarendon Laboratory, Oxford. This vaporizer is now being mass-produced at a cost four times lower than that if bench-produced. He stressed the need for closer contact between medical men and men of science, between clinical and laboratory workers.

Dr. S. E. Hollingworth, of the Geological Survey, illustrated how geologists are often not called in when sites for factories, camps and air-raid shelters are decided upon. This has led to considerable waste when the site is badly chosen in relation to drainage and water-supply. Dr. N. F. M. Henry, of the Department of Mineralogy, Cambridge, asked for a larger place in the war effort for geologists, stating that the British Army has only two geologists. He also discussed the Malayan situation and the consequent need for using the other mineral resources of the Allied countries.

There were many other speakers in the discussions, and they represented between them a considerable cross-section of industry. Mr. F. M. H. Markham, of the Central Register, answered some of their points regarding the utilization of personnel. Although he mentioned some cases where action is being taken or being considered, the Conference seemed quite definitely to show the need on the part of official committees for consulting the junior scientific worker.

The Conference was summed up most ably by Prof. J. D. Bernal. Starting on a note of urgency, he appealed for an absence of complacency on the part of men of science with regard to what Great Britain is doing. The suggestions which were put forward at the Conference would be taken up with the Ministries of Supply and Labour, but this would not be done without opposition. This opposition would come from industry and from the Government. The first is due to the prevalence of pre-war competitive ideas; while the second is purely conservative opposition to new ideas. However, the scientific way of doing things is forcing its way against that opposition, although the attitude in many of the departments is equivalent to sabotage. Dealing with the proper utilization of our man-power, he emphasized that the only consideration in the selection and posting of personnel should be ability. We should be blinding ourselves to facts if we thought this was so at present. He referred to the contributions in the Conference which had shown a widespread feeling that these scientific workers are not fully occupied, not doing the work they can most usefully do. The mechanism that exists at present is certainly not adequate if this situation holds. The Conference is not passing any resolutions; it is instead going to take appropriate action. The Association of Scientific Workers will collate the information and suggestions, and send delegations to appropriate Ministries. Scientific workers are at last co-operatively conscious of the job they have to do in society, and they will do it, and not stop doing it, when the War is won.

OBITUARIES

Dr. Walcot Gibson, F.R.S.

The death of Walcot Gibson will recall to many the memory of a many-sided, alert and virile personality. Born in 1864, he went from Bromsgrove School to Mason College (now the University of Birmingham) at a time when Lapworth, fresh from his triumphs in the south of Scotland, had been appointed to the chair of geology. Young Gibson, his first student, fell under the master's spell and his admiration for Lapworth remained with him as an inspiration throughout his career.

Following on a course of study at the Royal College of Science, Walcot Gibson undertook private geological work in South Africa during 1889–91 and in East Africa during 1891–93. The rest of his active life was spent in Great Britain in the service of the Geological Survey. Appointed temporary assistant geologist in 1893, he became geologist in 1901, district geologist in 1913, and in 1920 assistant director in charge of the Survey work in Scotland. In 1925 he retired and elected to live at Hythe, where he found leisure and opportunity to indulge in his love of gardening and painting. One of his chief pleasures was to welcome his old friends and former colleagues to his new home, and none who visited him but left with an increased regard for his sanity of outlook and balanced judgment on scientific matters. Soon after the outbreak of war he had to leave Hythe, and he died in Cambridge on November 28.

Walcot Gibson was part author of numerous Geological Survey memoirs dealing with the structure, succession and economic resources of many important coalfield areas in the Midlands and in South Wales: for example, Stoke-on-Trent (1902, with second editions in 1905 and 1925), North Staffordshire (1905), South Derbyshire and Nottinghamshire (1908), North Derbyshire (1913), South Staffordshire and Warwick (1919), Abergavenny (1902), Pontypridd (1903 and 1917), and Merthyr Tydfil (1904). He had learnt from Lapworth the necessity for careful and exact mapping and the value of what his exemplar termed the "zonal method of stratigraphy". He applied these lessons with scrupulous care to his studies of the detailed stratigraphy and palæontology of the Midland coalfields, and through his published works and the many personal contacts he made in the mining world he played an important part in guiding their economic development. A notable achievement in this direction was his study of the "Concealed Coalfield of Yorkshire and Nottinghamshire" (1913).

While much the greater part of Gibson's work was of an intensive, detailed character which perhaps only the specialist can fully appreciate, he won for himself many warm admirers among a wider public by the publication in 1920 of his book on "Coal in Great Britain". In this volume he brought together in a compact and attractive form the essential information regarding the British coalfields, and its success in filling a long-felt want may be gauged by the fact that a revised and enlarged edition appeared in 1925.

Walcot Gibson's services to science, particularly in the field of economic geology, were recognized by the award in 1924 of the Murchison Medal of the Geological Society and in 1925 by his election to the fellowship of the Royal Society.

M. Macgregor.

Prof. S. G. M. Ure

PROF. S. G. M. URE, whose death at the age of sixty occurred on December 25, was widely known as one of the pioneers of chemical engineering education in Great Britain. Born in 1881, he attended Allen Glen's School and later graduated at the University of Glasgow, where he took the degrees of B.Sc. in engineering and M.A. in mathematics and physics. On leaving the university he spent five years in the shipbuilding industry before taking up the educational work to which, with one short interval, the remainder of his career was devoted.

To those who were actively concerned with the vast production programme of the War of 1914–18 the difficulties which arose through the lack of trained scientific personnel made an abiding impression. They determined that, with the return of settled conditions, a concerted effort should be made to introduce into our universities a form of training which would produce men having the qualifications necessary to ensure the development of chemical industry on sound progressive lines. The names of Lord Moulton, Sir Arthur Duckham and Prof. Hinchley will long be remembered in this connexion; and, first as assistant to Hinchley, later as his successor, Prof. Ure took a notable part in the crusade.

In 1921 Ure was appointed lecturer in chemical engineering at the Imperial College of Science and Technology and in the following year he became a founder-member of the Institution of Chemical Engineers. From then until his death his energies were devoted unsparingly to the cause of chemical engineering training and to the service of the new Institution.

In 1932 he succeeded Hinchley as assistant professor of chemical engineering in the Imperial College, and in 1937 he was closely associated with the framing of an undergraduate course in the subject.

Ure was associated with many scientific activities. He was first elected to the Council of the Institution of Chemical Engineers in 1928 and became a vice-president in 1937; he served on numerous committees of the Institution and for ten years was editor of its *Transactions*.

D. M. NEWITT.

Dr. J. S. Owens

THE death of Dr. J. S. Owens on December 6 removes a most useful and public-spirited man of science. For nearly thirty years Dr. Owens has been the moving spirit in the investigation of atmospheric pollution on its quantitative side. He devised the instruments in use, and co-ordinated, tabulated and prepared for publication all the data on which the progressive changes in the amount of pollution in the atmosphere are evaluated.

Owens was born at Enniscorthy, Co. Wexford, Ireland, on July 28, 1871. He took the M.D. degree at Trinity College, Dublin, in 1896, but soon gave up medicine for engineering. He was a successful civil engineer chiefly in connexion with sea defence works and mining, and became consulting engineer to the San Domingo Mines in Portugal, and the Rio Tinto Copper Mines in Spain.

As the result of the Smoke Abatement Exhibition in 1912 a committee was formed for the systematic investigation of atmospheric pollution, and Owens became its secretary. In 1917 the work of this committee was transferred to the Meteorological Office and Owens was appointed part-time superintendent in charge of the Atmospheric Pollution Division. In 1927 the Department of Scientific and Industrial Research took over the investigation of atmospheric pollution from the Meteorological Office, and in order that the supervision of the instruments and the compilation of statistics should remain in his charge, Owens was appointed superintendent of observations.

For the quantitative investigation of atmospheric pollution Owens devised three main instruments and several instruments of lesser importance. The most widely used of these instruments was the standard deposit gauge. This consisted of a simple collecting basin having an opening of approximately four square feet exposed in the open on a stand at a height of four feet. All the pollution and rain which fell into the basin was collected and analysed, giving valuable information as to the amount and nature of the pollution deposited from the atmosphere. The second instrument was the automatic filter gauge for determining the amount of pollution contained in a given volume of air, and the third the jet dust-counter, for counting the number of particles of soot and other insoluble particles contained in the air. All three instruments have performed invaluable service, 123 deposite gauges and 16 automatic filters being maintained by municipalities and other public bodies in 1938.

Owens's inventive skill, conscientious compilation of records and personal enthusiasm have resulted in Great Britain being far ahead of any other country in knowledge of the pollution of its atmosphere—in this he has performed a valuable public service. Three days before his death Owens was awarded the Symons Gold Medal by the Royal Meteorological Society "for distinguished work done in connexion with Meteorological Science".

Mr. R. S. Herries

ROBERT STANSFIELD HERRIES died in December last at the age of eighty-one years. He took an active part in the work of the Geological Society, of which he was secretary from 1897 until 1905, and treasurer from 1921 until 1929; and of the Palæontographical Society, of which he was treasurer from 1914 until 1938. He was president of the Geologists' Association during 1906–8, and contributed the section on East Yorkshire to "Geology in the Field" published by the Association. Herries collaborated with the late H. W. Monckton in research on the Bagshot Beds of the London Basin. His geological collection (including the one made by his brother, the late Sir W. H. Herries) was presented to the Sedgwick Museum, Cambridge, with the exception of fossils from the Yorkshire coast, which he gave to the Yorkshire Museum, York.

WE regret to announce the following deaths:

The Right Hon. the Earl of Berkeley, F.R.S., on January 15, aged seventy-six.

Dr. C. Delisle Burns, formerly Stevenson lecturer in citizenship in the University of Glasgow, on January 22, aged sixty-two.

Prof. R. S. Seton, emeritus professor of agriculture in the University of Leeds, on January 12, aged seventy-four.

NEWS and VIEWS

Science and the Classics

We had thought that the old controversy between science and the classics had been finally disposed of, but a resolution submitted on January 22 to the Lower House of Convocation of Canterbury came perilously near raising it once more. The resolution was moved by Dr. E. G. Selwyn, dean of Winchester, who urged that the revival of classical education is necessary for the good of the Church and of the nation. The classical outlook, in his view, stands for humanism, which includes the belief in absolute standards of conduct and in individual personality. Classics must, however, be made less specialized, and more room must be found for science. On the other hand, it must be recognized by science that concentration on material things imposes certain limitations. Thus in Dr. Selwyn's view, although modifications in the classical type of education are desirable, science would be admitted almost as a poor relation, presumably in deference to the needs of the times.

While no broad-minded man of science would wish to deny that an educational system based on science alone has very definite shortcomings, it is surely out of the question to suggest that any useful purpose can be served by relegating science to a subordinate position in twentieth-century studies. Science and the classics both have a place in modern culture, but should competition arise, it is to be expected that science should be given the greater share of attention. Dr. W. R. Matthews, dean of St. Paul's, discussing the resolution, emphasized that scientific studies have provided openings for many minds not naturally able to profit by classical studies, and pleaded for an all-round education including science. Eventually, the original resolution was modified and carried, with two dissentients, in the following form: "That this House, while recognizing the great value of scientific and other modern studies, is of opinion that wider recognition of the importance of classical education is urgently needed in the interests of the Church and nation and for the maintenance of a stable civilization and culture after the war."

Endeavour

Imperial Chemical Industries, Ltd., has just issued the first number of a new quarterly journal, *Endeavour*, which is designed to record the progress of the sciences in the service of mankind and as evidence of British scientific enterprise. The issue, which is priced at 5*s*., is well produced, carrying forty-eight pages of text, and well bound, with a drawing on the cover of the barque *Endeavour* which, commanded by Captain Cook, was sent out in 1768 by the British Admiralty to chart the South Pacific Ocean and observe the transit of Venus. After a brief statement by Lord McGowan of the purpose of the new journal, the number opens with a short article on "Science and the Community" by Sir William Bragg. The main feature of this initial number is Dr. H. Spencer Jones, the Astronomer Royal, on the "Distance of the Sun". Other articles are equally as authoritative, as may be judged from the following selection: Dr. C. H. Waddington, "The Epigenotype"—the author's name for the whole complex of development processes which lie between genotype and phenotype; J. G. Crowther, "Sciences in the U.S.S.R."—though the author confines himself to the physical sciences; we suggest that this be followed by one on the biological, agricultural and medical sciences, for which the world has much to thank the U.S.S.R.; A. L. Bacharach, "The Manufacture and Use of Vitamins"—in which emphasis is placed on British contributions to this important branch of science; G. V. Jacks, "Prospects for Soil Conservation"; F. Fairbrother, "The Cyclotron"; etc.

The edition of *Endeavour* before us is in English. There are to be other editions in Spanish, French and German, and a total distribution of 25,000 copies is contemplated to be sent to colleges, scientific institutions, universities and prominent individuals in foreign countries and the British Empire. The influence of the journal will therefore be much more than national, and we warmly welcome it since, as Sir James Jeans says in a communication, it "will help to make the beneficent advances of science the common property of all nations and of all races". As Lord McGowan points out, *Endeavour* will help to throw the light of science overseas especially to those parts of the globe where intimate contact with Great Britain is at present more difficult to maintain. Emphasis is laid on British scientific work, but as Lord McGowan says, the journal will not be marked by any narrow insularity, as is sufficiently guaranteed by the contents of this inaugural number. We congratulate the editor and Imperial Chemical Industries, Ltd., on this remarkably attractive and efficient achievement and wish it the success which its cause so richly deserves.

Wealden Iron Ore

It is well known, as was recently mentioned in a letter in *The Times*, that iron ore occurs in various parts of the Weald, where mining and smelting were carried on by the Romans, and were continued until the nineteenth century. Smelting ceased in 1828, and mining in 1858. The Wealden iron industry was highly decentralized, and consisted of a large number of small works. It bears no comparison with that of modern times. E. Straker, in his book "Wealden Iron" (1931), lists more than 225 furnaces, forges and bloomeries spread in time over several centuries. The life of many of these was short. The largest works were at Ashburnham; of these, Mr. Straker records that the annual output was about 350 tons. Wealden iron ore is usually a clay-ironstone and occurs in nodules and in thin beds up to a maximum of two feet in thickness, interbedded with shale. Sometimes a pale grey sideritic rock is present. The Wadhurst Clay furnished the bulk of supplies, but the other Wealden formations, and also a ferruginous superficial deposit—an ironstone 'pan' or 'shrave'—yielded their quota. Much was mined from bell-pits, which were rarely more than twenty feet deep, although some were upwards of forty feet in depth. Shale excavated with the iron ore was sold as 'marl' for agricultural purposes; indeed, agriculture and iron ore working seem to have gone hand in hand in many instances. Many quarries were opened primarily as 'marl pits', but all ironstone encountered was separated and sold when sufficient had been accumulated.

The last attempt at exploiting Wealden iron was at Snape Mine, Wadhurst, during 1857–58, ore being sent to Staffordshire. Two beds were worked, one up to two feet in thickness. Both beds were irregular in occurrence, sometimes dying out completely for a distance. The roof was bad, and required timbering. A long account of the Wealden iron industry is given by C. Gould in the Geological Survey Memoir "The Geology of the Weald" (1875), compiled by Topley, and additional information, notably an analysis of the Snape Wood ore, in the Geological Survey's "Special Reports on the Mineral Resources of Great Britain", 12 (1920). This analysis, made in 1908 for J. W. Gregory by Messrs. R. R. Tatlock and Thomson, showed the following, in percentages: FeO, 30·42; Fe_2O_3, 10·10; SiO_2, 26·10; CaO, 0·86; SO_3, 0·06. These show about 30·66 per cent of metallic iron, but the high percentage of SiO_2 would prevent the use of this stone as an iron ore. On the contrary, the Ashburnham ore showed FeO, 42·08; Fe_2CO_3, 6·85; SiO_2, 6·46; CaO, 3·87; SO_3, 0·2; giving 37·49 per cent of metallic iron, with relatively little silica. Unfortunately not only are the beds of ore thin, but they are also very irregular in their composition, and there seems little prospect that ore of this kind, which occurs in thin beds and can only be excavated together with a large amount of shale, could be profitably worked by existing methods. The usable reserves of iron ore in the Weald are, in the present circumstances, negligible.

Awards of the Geological Society of London

THE following awards of the Geological Society of London have recently been announced: *Wollaston Medal* to Prof. R. A. Daly, Sturgis Hooper professor of geology in the Museum of Comparative Geology at Harvard University, in recognition of his fundamental researches in many branches of geology, especially those concerned with the origin of igneous rocks, the constitution of the interior of the earth, and the controls of coral-reef formation; *Murchison Medal* to Prof. H. H. Swinnerton, professor of geology in University College, Nottingham, for his stimulating contributions to the philosophy of palæontology; *Lyell Medal* to Mr. W. S. Bisat, for his studies in the stratigraphical palæontology of Carboniferous rocks; *Wollaston Fund* to Dr. E. S. Hills, for his contributions to Australian palæontology and geology; *Murchison Fund* to Dr. K. C. Dunham, for his investigations into the mineral deposits of the North of England; a moiety of the *Lyell Fund* to Dr. S. R. Nockolds, for his mineralogical and petrological work and his contributions to the study of assimilation processes; a second moiety of the *Lyell Fund* to Dr. J. Shirley, for his researches in palæozoic palæontology and stratigraphy.

Institute of Metals: Platinum Medallist

THE Platinum Medal of the Institute of Metals for 1942 has been awarded to Mr. W. Murray Morrison, vice-chairman and managing director of the British Aluminium Co., in recognition of his outstanding services to the non-ferrous metals industries. Mr. Morrison is an original member and a fellow of the Institute of Metals, on the Council of which he served for sixteen years—in the last two as vice-president. He may be described as the father of the aluminium industry in Great Britain, having been associated with the British Aluminium Co. since its inception in 1894. He is also the pioneer of the developments of Highland water-power upon which depend the electro-metallurgical operations for the production of aluminium at three great Scottish factories.

Institution of Mining and Metallurgy: New President

MR. J. ALLEN HOWE has been elected president of the Institution of Mining and Metallurgy for the year 1942–43. Mr. Allen Howe was educated privately and at the Royal College of Science, and holds the London B.Sc. degree. For a year he was demonstrator in geology at the Royal College of Science and Royal School of Mines, and in 1901 was appointed to H.M. Geological Survey, where he served for thirty years on the field staff and as curator of the Museum of Practical Geology, and from 1922 onwards as assistant director. During his service he took an active part in stimulating the economic side of the Survey's work, and he is the author of several works mainly dealing with building stone, broken stone, and refractory materials. On these and other subjects he has made numerous contributions, including many articles on topographical geology and stratigraphy in the Encyclopædia Britannica (thirteenth edition). He was a member of the International Conferences on Testing Materials, and was for a number of years adviser on stone to H.M. Office of Works and since 1918 to the Imperial War Graves Commission. He was a member of the Committee on Coal Conservation and the Imperial Economic Committee. Since 1931 Mr. Allen Howe has practised as a consultant in economic geology.

Chronica Botanica

THIS international plant science news magazine, formerly published in Holland, continues to appear now from Waltham, Mass., U.S.A. Vol. 6, Nos. 17–18 appeared in November 1941 and is an exceedingly interesting number. Under the heading "Nomina ad Infinitum" Dr. F. C. Bawden asks for a more vigorous effort to rationalize procedure in the naming of virus diseases of plants, and then in the "Plant Science Forum" a number of subjects of general botanical interest are raised by well-qualified contributors. Very general interest will be aroused by a brief note from Dr. W. C. Darrah on the fossil embryos in Iowa coal balls; in particular, in the record of the discovery of the embryo and young seedling of a Lepidocarpon. There then follows a series of brief "Progress Reports" on plant science in Latin America, for example, on forestry in Mexico (Meyer), natural resources of Costa Rica (Skutch), etc.

International activities naturally do not bulk largely in the present day, but there is a note on the International Forestry Centre, which, established in May 1939 as a division of the International Institute of Agriculture, held its third meeting in March 1940 in Berne. The "Chronicle" of events has a very full statement of Kew activities in view of the centenary of the Royal Botanic Gardens in 1941: there is an interesting account also of the All-Union Agricultural Fair held in Moscow during 1939 and 1940 and again re-opened in the early summer of 1941. Details of the activities and vicissitudes of various botanical departments under present disturbed conditions make interesting reading to botanists, and similarly the many changes in personnel chronicled will often bring news of colleagues to readers. Very naturally the editors have contemplated closing this venture with the completion of vol. 6, and the extension of the War to the Pacific will possibly force them to reconsider their present decision to proceed at least with the issue of Vol. 7 in the form of twelve numbers to be issued once every three months. If publication can be continued, however, this chronicle is probably more valuable to the botanical world under present conditions than even in normal times.

Rapid Glass-house Repair

THE problem of repairing small holes in glass-houses both rapidly and economically has confronted many growers since the outbreak of war. After a thorough investigation of the matter, the Cheshunt Experimental and Research Station recommends the use of Bostik B. glazing compound, manufactured by the B. B. Chemical Co., Ltd., Ulverscroft Works, Leicester. The glass must be clean and perfectly dry. An extending nozzle is fitted to the Bostik tube, by means of which a thick flat continuous bead of the compound is delivered. This is allowed to dry for five or six minutes. The piece of glass which is to serve as a patch is then pressed lightly down on to the bead and a further film of Bostik applied around the outer edge of the patch to complete the seal. Glass substitutes can be used for patching instead of glass, and cracks can be satisfactorily sealed by a bead of the compound. All particulars are given in War-Time Notes No. 1, issued with the annual report of the Cheshunt Research Station for 1940.

Health of Eire

ACCORDING to the report of the Department of Local Government of Eire for 1939–40, 1939, as in all parts of the world from which statistics are available, was a record year in Eire owing to the low prevalence and fatality of acute infectious diseases. There were only 2,779 notifications of scarlet fever with 43 deaths in 1939, both figures being much the lowest on record. There were 2,097 cases of diphtheria with 245 deaths which accounted for nearly two thirds of all deaths from endemic infections. The fatality rate of diphtheria, as in all parts of the world, unlike that of measles, whooping-cough, and scarlet fever, showed no tendency to fall. There was an apparent increase in the mortality from tuberculosis, but this was probably accounted for by an improvement in notification.

Vital Statistics of Switzerland

RECENT statistics show that the decline in the birth-rate in Switzerland still continues. In 1939 it exceeded the death-rate by only 3·4 per thousand inhabitants as compared with 3·6 in 1938, 4·2 in 1936, 5·6 in 1930, 6·5 in 1920, 9·9 in 1910 and 11·5 in 1903. The death-rate reached its lowest record in 1934 and in 1937 with 11·3, but rose to 11·6 in 1938 and 11·8 in 1939. Since 1871, with few exceptions, the marriage-rate has fluctuated between 6·8 and 7·9, and the marriage age of single men has risen from 28·5 to 28·9, and of single women from 26·1 to 26·7.

Mechanism of the Sun

THE presidential address to the British Astronomical Association was delivered on October 29 by F. J. Sellers, and dealt with the sun. Mr. Sellers is director of the Section of the Association dealing with the sun, and has done a considerable amount of research along certain lines. He has designed a very useful form of spectroscope and also a form of vibrating slit mechanism for the spectro-helioscope, and is a keen observer of solar phenomena. His address covered a very extensive field; here it is sufficient to say that the most up-to-date information on nuclear reactions in the interior of the sun, sunspots, the corona, chromospheric eruptions, etc., was discussed. The address is printed in full in the *Journal of the British Astronomical Association* (52, 1; 1941).

The Night Sky in February

THE moon is full on February 1d. 9h. 12m. and new on February 15d. 10h. 2m. U.T. Lunar conjunctions with the planets occur on the following dates: Venus on February 14d. 0h., Venus 5° N.; Mars on February 22d. 1h., Mars 6° N.; Saturn on February 22d. 3h., Saturn 3° N.; Jupiter on February 23d. 19h., Jupiter 5° N. Mercury is an evening star until February 8, then a morning star. Venus is a morning star, and Mars, Jupiter and Saturn are evening stars. On February 24d. 2h. Mars is in conjunction with Saturn, Mars being 3·5° N. Mars, Jupiter and Saturn are still well placed for observation during the month. The planet Uranus, seen as a 6th magnitude star, is in the western part of Taurus and about 5° south of the Pleiades. In the latitude of London the day lengthens by about 1¾ hours during the month.

Announcements

DR. SELIG HECHT, professor of biophysics at Columbia University, has been awarded the Frederic Ives Medal of the Optical Society of America for "distinguished work in the field of optics".

THE Pan-American League for the Control of Cancer will meet this year at Buenos Aires under the presidency of Prof. H. Angel Roffo.

THE International Commission on Continental and Oceanic Structure of the International Union of Geodesy and Geophysics (chairman, Dr. R. M. Field) has found means to continue in operation the Scoresbysund seismological station, originally run in connexion with Danish stations. Funds were granted by the American Philosophical Society of Philadelphia, which will supply paper and other photographic materials for another year of operation. The supplies have been shipped.

THE Rugby Branch of the Association of Scientific Workers is conducting a series of lectures and meetings, held on Thursdays, on the general theme, "The Coming Post-War World". Among the speakers are Prof. V. H. Mottram on the social implications of dietetics, Capt. J. Langdon Davies on scientific invention at the service of the community, and Prof. A. St. G. Huggett on the social basis of physical and psychological health. Particulars can be obtained from the honorary secretary, J. B. Laurie, Upper Rainsbrook, Ashlawn Road, Rugby.

THE Clough Memorial Research Fund was instituted in 1935 for the purpose of encouraging geological research in Scotland and the North of England. The North of England is defined as comprising the counties of Northumberland, Cumberland, Durham, Westmorland and Yorkshire. Under the terms of administration of the fund a sum of approximately £30 is available annually. Applications for grants are invited for the period April 1, 1942—March 31, 1943, and should be made to the Secretary, Clough Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh, not later than March 1.

Uplift in Dams

In the design of masonry or concrete dams, the uplift due to the penetration of water into the structure is a factor which up to the present has not been completely investigated. Previous experiments intended to solve the problem gave rise to much controversy as to the interpretation of the results[1].

In the following experiments, which were made for the Projects Department of the Ministry of Public Works, Egypt, results have been obtained which are independent of theories about the internal structure of the material.

The apparatus consists of a test chamber in which a cylindrical test-piece of concrete of length 60 cm. and diameter 15 cm. is placed in such a manner that one of its extremities projects beyond the container. The test chamber is connected to a water supply the pressure of which can be raised by an accumulator, and this water pressure is applied to the middle part of the outer surface of the test-piece. At the same time the test-piece can be subjected to an axial compression or tension by means of a system of levers and weights. This force varied from 5 tons compression to 2 tons tension. The test-piece has a hole of 4 cm. diameter along its axis to allow air to escape from the pores, but more important, to make certain that the external water pressure is acting right through the specimen when failure occurs. In making an experiment, the longitudinal force N is first applied, and then the pressure of the external water is raised to a pressure P and maintained constant while water percolates through the specimen and produces a pressure Q in the axial cavity. The external pressure is raised by slow steps, depending on the rate of rise of Q, until fracture takes place. The whole experiment takes from three to five days to complete.

To understand the principle of the experiment we imagine the simple case where a solid cylinder, the area of cross-sections of which is S, is compressed by a longitudinal force N and finally broken after a long time by the external water penetrating the material under pressure P. The pressure P, owing to the porosity of the substance, acts over a fraction f of the cross-section: let the resistance of the material just before breaking takes place be z. Then we have

$$PfS = z + N,$$

where we do not know either f or z.

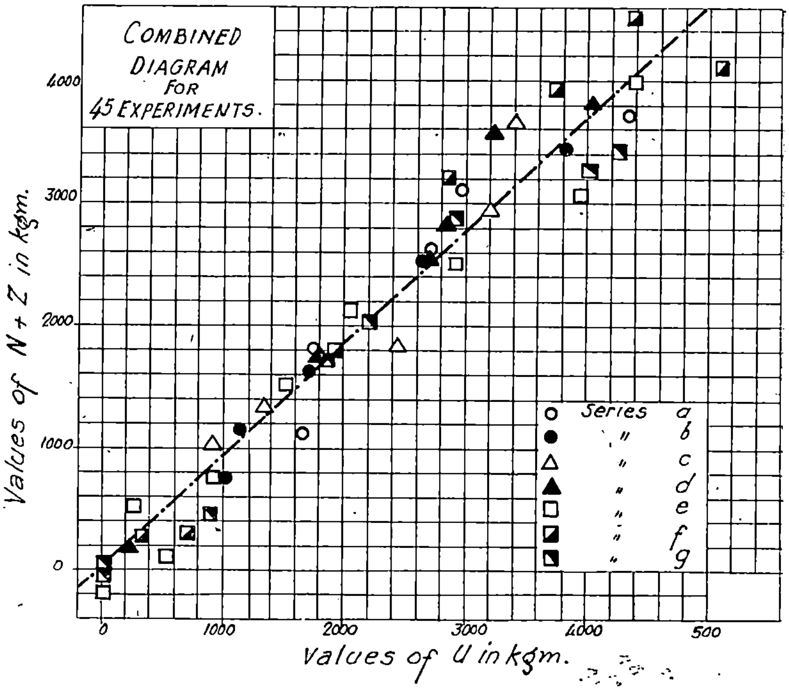
By making a number of experiments with different values of N, we obtain a series of equations from which we can determine f and z.

In the experiments, the pressure p in the interior of the test-piece varies from P outside to Q inside, the two being not necessarily equal. PS is therefore replaced by $\int p dS = U$, the value of which is:

$$U = QS + (P - Q)S\left[\frac{D^2}{D^2 - d^2} - \frac{1}{2\log D/d}\right].$$

While this formula was developed from the elementary theory of laminar flow, it was also verified empirically and found fairly accurate both in regard to the experiments under review and other experimental investigations[2].

For determining the coefficient f, some six or ten test-pieces are made of the same material and these are broken each with a different external load N. The values of U are then calculated and plotted against N. Allowing for the unavoidable variation of the test-pieces, the relation between U and N is found to be linear. The coefficient f is therefore given by the slope of the line expressing this relation. Contrary to what might have been expected, f was not very much affected by the materials or methods used in making the specimen, and only varied from 0·85 to 0·98, with a mean value of 0·92. In consequence of this, it has been possible to plot the results of the forty-five tests made up to the moment on a single diagram.



The materials used and the individual coefficients found were:

Series	Proportion of cement to sand and to coarse aggregate (volumes of dry materials)	Type of sand	Type of coarse aggregate	Water-cement ratio	f
a	1·0—1·6—1·1	Average	Crushed Granite	0·40	0·88
b	1·0—2·7—3·3	,,		0·93	0·92
c	1·0—1·1—2·2	,,	,,	0·50	0·95
d	1·0—2·3—4·2	,,	,,	0·72	0·99
e	1·0—1·7—4·6	Coarse	,,	0·58	0·87
f	1·0—1·1—2·2	,,	Gravel	0·40	0·96
g	1·0—2·8—0·0	,,	—	0·44	0·85

The probable deviation of a point from the mean line is about ± 200 kgm., while the probable error of f is only $\pm 0{\cdot}02$.

The observations were examined statistically for systematic effects due to varying ages of the specimens, or to changes of the tensile resistance Z due to compressive ring stresses at right angles to the main axis, or to variation of the superimposed load N. No effects of this nature were found.

The porosity of some specimens was determined by weighing and drying, and was always less than 20 per cent. The fraction of the area of cross-section over which the internal pressure acts can therefore have nothing to do with ordinary porosity, and the results of the experiments tend to support Prof. Terzaghi's views. They may lead to changes in the methods of allowing for uplift in the design of dams.

Further work is going on, and it is intended later to publish a full account of the work in an Egyptian Government publication.

Surnames and Blood Groups, with a Note on a Probable Remarkable Difference between North and South Wales

Two years ago[1] Prof. R. A. Fisher and Dr. Janet Vaughan suggested that recent population movements in Great Britain can lead to significant association between surnames and blood groups. They found that out of 11,377 donors resident in the Slough area 591 bearing Welsh family names were significantly lower than the remainder in the frequency of A. Counts of blood groups donors now in progress have yielded striking proof of the value of this simple technique; and incidentally have revealed a startling and (to me) unexpected difference between North and South Wales.

Taylor, Race and Fisher[2] have given figures which illustrate the great variability in the frequency of A in the British Isles: Southern England, $O = 45$ per cent, $A = 43$ per cent; Northern England, $O = 48$, $A = 40$; Scotland, $O = 52$, $A = 34$. Haldane[3] gives the following figures for an Irish sample: $O = 56$, $A = 30$. These figures will serve as a standard of comparison for those given in the present communication.

A sample of 2,550 Welsh donors, drawn from Caernarvonshire, Denbighshire and Flintshire, gives: $O = 48$ per cent, $A = 40$ per cent. When, however, the sample is divided into 1,132 donors with Welsh family names and 1,418 donors with non-Welsh family names, the Welsh donors give $O = 51$, $A = 36$: the non-Welsh donors give $O = 45$, $A = 43$. The difference is highly significant. (The high proportion of non-Welsh names in the sample is largely due to the North Welsh coastal area being strongly represented.) Here, then, the family name technique has unmasked the diluting effect of recent migration and has revealed an important difference in blood groups between two partially isolated populations inhabiting the same area.

Another positive result was found when donors with Highland Scottish and Irish names living in the Bristol area were compared with the remainder. 40,740 donors in this area have given $O = 44$, $A = 44$. 778 donors with characteristically Highland or Irish names have given $O = 49$, $A = 38$, again a highly significant difference.

During the course of this work it became apparent that North and South Wales were strangely different. The first piece of evidence was that 3,242 donors with Welsh names drawn from the Bristol sample were as high in A as the remainder. Yet much of this immigration must be very recent, for the proportion of men was considerably higher among the Welsh donors. As Welsh names in Bristol must be overwhelmingly of South Welsh origin, the North Welsh material was re-examined, the Welsh names being classified according to their relative frequencies in North and South. I relied on Guppy's "The Homes of Family Names"[4] in making the selection. It was found that donors with names more characteristic of South Wales were significantly higher in A. Prof. Fisher has very kindly provided some figures relating to South Wales. 1,765 Cardiff donors give $O = 45$, $A = 43$; 537 Swansea donors give $O = 45$, $A = 40$.

Further work is in progress, but even on the evidence now available it seems probable that while the North Welsh are, as regards blood groups, kin to the Highland Scots and the Irish, the Southern Welsh are almost indistinguishable from the Southern English. Surnames came into common use in Wales during Tudor times, so it appears likely that the peoples of the North and South who at that time adopted the same family names were already very different; after all, perhaps, not such a surprising result in view of the different influences known to have affected the two parts of the country and the great difficulties of communication between them.

Fisher and Vaughan[1] have undoubtedly directed attention to a simple and valuable technique, and it is much to be hoped that blood group investigators will avail themselves of it in connexion with appropriate material. The additional clarification thus made possible may often be considerable. The usefulness of the method is not, of course, confined to blood group studies.

When these investigations are complete it is intended to report them fully in the *Annals of Eugenics*. I will then take the opportunity of expressing my great indebtedness to all those who have so kindly provided the facilities which have made the work possible.

Vernalization of Mustard

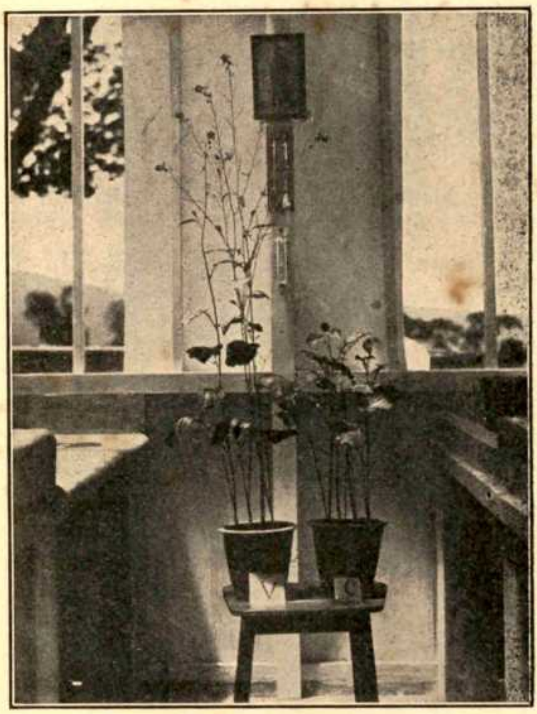
In our preliminary report[1] on vernalization of mustard (*Brassica juncea*, Hooker Type 27) it was shown that even seeds previously soaked which remain unsplit during the period of chilling are vernalized. Though the degree of vernalization induced by the same dose of chilling is greater in seeds which sprout during the period, only unsplit chilled seeds offer practical agricultural possibilities, since the latter can be dried without impairment of subsequent germinating capacity. Four other strains of Indian mustard—Types *C*.9, *C*.11, Raya *O.B*.1, and yellow sarson—have all since been found to respond to vernalization. For the same dose of chilling, the shortening of the vegetative period (from sowing to opening of the first flower) of plants from unsplit chilled seeds have been found to vary according to the strain.

Most of our vernalization experiments with mustard have been carried out with Type 27, in which maximum vernalization is induced in unsplit seeds when chilled for six weeks. Further prolongation of chilling up to 365 days does not induce any higher degree of vernalization, nor any devernalization.

Lojkin[2] found that vernalized seeds of winter wheat when air-dried at 1° C. and 15° C. were partially or completely devernalized, and Gregory and Purvis[3] observed complete devernalization when fully vernalized seeds of winter rye were dried for twenty weeks. Drying vernalized unsplit mustard seeds, however, is surprisingly without effect. For it has been found from a long series of sowings, spread over a period of two years, of the same batch of dried vernalized unsplit seeds, that the vegetative periods of *V*-plants sown on similar dates in two successive years (subjected to more or less the same after-sowing temperature ranges and photo-periods) remained strikingly constant. Thus, in the first sowing (April 24, 1939) when the *V*-seeds had been dried for twenty-one days only, the observed vegetative period was 31·9 ± 0·54 days (mean of eight plants), and in the ninth sowing, April 24, 1940, when the period of drying was 387 days, the vegetative period observed was 30·5 ± 0·41 days (mean of 15 plants). Similarly, in the eighth sowing, March 20, 1940, and the twentieth sowing, March 28, 1941, the respective periods of drying were 352 and 725 days, and the vegetative periods of *V*-plants were 37·5 ± 1·48 days (mean of 4 plants) and 34·9 ± 0·57 days (mean of eight plants). These results indicate that drying of vernalized unsplit seeds of mustard for a period of 725 days did not induce any devernalization. In the case of vernalized intact fruits of winter rye also, which Gregory and Purvis[2] obtained by chilling the embryo in the ear during seed formation, drying did not induce devernalization. Thus it would appear that when the growth of the embryo is confined within the elastic limit of the seed-coat, chilled seeds can be dried without resultant devernalization.

Results of seasonal sowing (October 1939) of fully vernalized unsplit seeds of mustard along with the controls in replicated field plots show that under the climatic conditions of Almora a significant earliness in flowering of 25·4 days (31·3 per cent) in Type 27, 20·3 days (23·8 per cent) in *C*.11, and 29·57 days (31·3 per cent) in *C*.9 can be obtained by the use of vernalized unsplit seeds.

The observed vegetative periods of *C*- and *V*-plants (Type 27) grown throughout the year under different seasonal temperature ranges but under similar effective photo-periods indicate that: (1) Mustard Type 27 has no obligatory low-temperature requirement for the *first phase* of development, for plants from untreated control seeds flowered when the minimum night temperature was 20° C. or higher. On the other hand, under all different after-sowing temperature ranges studied (max. day temperature 44°–10° C. and minimum night temperature 22°–1° C.) and of photo-periods (10–16 hr.), plants from fully vernalized unsplit seeds flowered significantly earlier; (ii) Mustard Type 27 flowers under photo-period of 10 hr. as well as 16 hr.; but under all temperature ranges studied both *C*- and *V*-plants flower significantly earlier with increase of photo-period from 10 hr. to 13 hr. for the initial three weeks; (iii) within limits, the effect of low temperature during the *first phase* of development and of increased photo-period during the *second phase* in shortening the vegetative period of mustard is of a *quantitative* nature. Under similar temperature ranges *V*-plants under photo-period of 10 hr. and *C*-plants under photo-period of 13 hr. or more have been found to have similar vegetative periods. The original concepts of Lysenko's theory of phasic development of annual seed crops[4] therefore do not seem to apply to Mustard Type 27, either with regard to the obligatory nature of changes produced by low temperature during the *first phase* or the strict dependence of each phase on the completion of the preceding one.



MUSTARD TYPE 27. PLANTS IN POT *V* ARE FROM VERNALIZED UNSPLIT SEEDS CHILLED SIX WEEKS, DRIED SIX DAYS: IN POT *C* ARE PLANTS FROM CONTROL, UNTREATED SEEDS. BOTH SOWN ON JULY 11, 1938.

The observed vegetative periods of plants from the progeny of seeds vernalized for three successive generations of Mustard Type 27 do not indicate any transmission of the effect of vernalization to the offspring. But low temperature during the period of seed ripening has been found to produce partially vernalized seeds.

A detailed report of this work is being published in a forthcoming number of the *Indian Journal of Agricultural Science*. Expenses of the investigation have been met by grants from the Elmgrant Trust of Dartington, Totnes, and the Imperial Council of Agricultural Research, New Delhi.

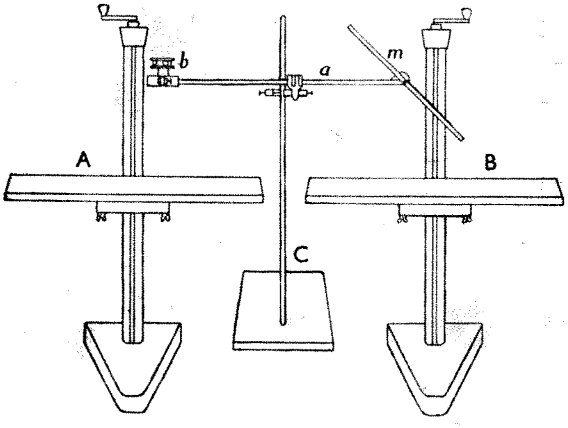
Use of the Camera Lucida for Transcribing Diagrams

INTERESTING modifications of the camera lucida for making larger drawings were recently described in these columns[1]. A novel use to which I have put this apparatus may also assist biologists in their work. Teachers and research workers in biology who regularly abstract information from the original literature must have felt the need for obtaining accurate copies of diagrams and figures which accompany the text of publications. Various methods of transcription are known; but apart from tracings, which leave much to be desired, they call for apparatus which is rarely available. The following method of using an ordinary camera lucida of the Abbe type for transcribing diagrams has the advantage of permitting enlargement or reduction of the original.



Two small drawing boards are provided on their lower surfaces each with a U-shaped support of ⅜ in. iron rod having two projecting lugs which will fit into the clamps of a pillar stand such as is used in physiological experiments. The stands to which the boards have been clamped are placed to the left and the right (*A* and *B* in accompanying figure) of an ordinary retort stand (*C*) the clamp of which grips the arm (*a*) of the camera lucida so that the prism and light filters (*b*) of the apparatus overhang the left board (*A*) while the mirror (*m*) overhangs the right board (*B*). The distance apart of the pillar stands is determined by the length of the arm (*a*), the vertical level of which is in turn determined by the work in hand. Each board can be raised or lowered separately by rackwork through a vertical distance of approximately eighteen inches.

The figure which is to be copied is placed upon board *A* and covered with a sheet of plate-glass, and the paper on which the copy is to be made is pinned in position upon board *B*. The drawing is made exactly as if the camera lucida were being used for microscopic work, that is, the object is viewed through the perforated prism at *b* (as is the image of a microscopic object) and is seen in relation to the image of the paper which is superimposed upon it as a result of light reflexion from the mirror and the prism.

When the boards *A* and *B* are set at the same horizontal level the copy will be enlarged (my apparatus gives a ratio of approximately 4/3), but by setting the boards at different levels various amounts of reduction or enlargement can be achieved. The lowering of board *A* and the raising of board *B* favour reduction and vice versa. With ordinary equipment I obtained at the two extremes a reduction by one half and an enlargement of five diameters respectively. The methods advocated by Harding for enlarging drawings may be used to increase this range.

The ordinary light screens with which the camera lucida is provided also serve when the apparatus is used for the transcription of diagrams, but modification of the lighting arrangements to suit individual needs is advantageous. Manipulation of bench lamps will remove any lighting difficulties.

The alternate focusing of the eye on the diagram and the copy may involve strain, especially when the apparatus is being used for reduction or enlargement. This can be avoided by placing a biconvex spectacle lens above the prism of the camera lucida. When preparing enlarged or reduced copies of the original diagram, I use lenses of 13 in., 18 in. and 20 in. focal length, with the alleviation of eye strain and with greater ease of working.

Some difficulty might be experienced when the figures which are to be copied occur in large volumes or manuscripts. This can be overcome by the use of a sliding mirror (*m*) on an appropriately lengthened arm (*a*).

This arrangement of ordinary laboratory equipment may be used for preparing graphical records of published diagrams in original papers and for accurate diagrammatization of complex figures for teaching purposes. I have used it for transcribing unequal original diagrams of related Trematoda to the same size in the copy[2]. This means of cancelling out absolute size differences revealed *relative* differences which are of some taxonomic importance, but which were obscure in the originals.

RESEARCH ITEMS

The European Earwig in America

In Technical Bulletin 766 (1941) issued by the U.S. Department of Agriculture a very full account is given of this insect and of methods for its control. The authors, S. E. Crumb, P. M. Eide and A. E. Bonn, describe in the first place its distribution, where it occurs on both the eastern and western sides of North America. It appears to have been first noticed in Rhode Island, in the west, in 1911 and, in the east, at Seattle in 1907. It has also become established in British Columbia, where it was first noted in 1919. The survival and abundance of the insect are dependent mainly on the amount of desiccation to which it is subjected, it being best adapted to cool latitudes. It is omnivorous, but prefers the lower plants (algæ, lichens, etc.) to most of the higher types of vegetation. The eggs are deposited in cells in the soil in January and February and the adults begin to appear in July. A proportion of the females re-enter the soil in about May and deposit a second batch of eggs. The female watches over the eggs and first instar nymphs and will fight savagely in their protection. The earwig rarely flies, but the authors state that they have noticed as many as twenty flights in one day. Although so pronouncedly nocturnal in many of its habits, it seems to fly mostly in bright warm sunshine. It is considered that the best method of repressing this insect is by means of poisoned baits. The one found most successful on a large scale consists of a mixture of wheat bran, twelve parts by weight and one part each of sodium fluosilicate, and fish oil.

Beetles of the Family Lathridiidæ

Dr. H. E. Hinton of the Department of Entomology, British Museum (Nat. Hist.), has contributed an article (*Bull. Ent. Res.*, November, pp. 191–247) on Lathridiid beetles of economic importance. Altogether about thirty species of this family have been recorded among stored food products or have occurred in warehouses, granaries or mills. Among these, ten species have not hitherto been recorded from Britain. Under each species are given summaries of its distribution, life-history and the literature relating thereto. Also, for the first time, complete life-histories of five species have been worked out, and the larval and pupal stages are carefully figured. The family as a whole comprises about 520 species, all small (1–3 mm. long) and they, together with their larvæ, are found in mouldy plant and animal substances, in mycetozoa and fungi, in vegetable detritus, under bark and stones and sometimes in ant and termite nests. Both stages apparently only feed on mycetozoa and fungi, particularly moulds. It appears that none of the species dealt with is responsible for any direct injury to food, since they are exclusively fungus feeders. When present in considerable numbers, they may cause a certain amount of damage by fouling food substances with their fæces. Since they are able to transmit moulds to uncontaminated foods, they may in this way entail losses. Control measures comprise drying, heating, or fumigation. Any measures that will eliminate fungi will also be effective in getting rid of Lathridiid beetles.

Somatoplastic Sterility

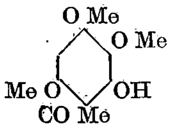
R. A. Brink and D. C. Cooper (*Genetics*, 26, 487–505; 1941) have studied the development of seeds in the cross *Nicotiana rustica* × *N. tabacum*, which rarely produces viable seeds, and in *N. rustica* × *N. glutinosa*, in which no viable seed is produced. They find that endosperm growth is retarded, hyperplasia of the nucellus occurs, and the cells of the integument between the apex of the vascular bundle and the chalazal pocket do not differentiate into conducting tissue. Where the endosperm and the embryo do grow in the first cross, it is found that they grow at the expense of the neighbouring integumental cells, which are thereby depleted of their contents. The authors consider that this somatoplastic sterility is of widespread occurrence in economic plants such as apples, pears, or seedless fruits, and is of great importance in regard to such phenomena as June-drop, poor cropping and varietal differences in fertility.

Chromosome Homologies in the Genus Drosophila

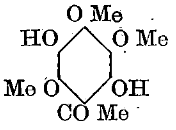
The result of the intensive experimental work of the last twenty years is bearing fruit in providing an insight into the genetical composition of the chromosomes of the various species of Drosophila. In an important paper, A. H. Sturtevant and F. Novitski (*Genetics*, 26, 506–517; 1941) have summarized the facts from more than thirteen species of Drosophila. Taking the arm from the centromere to the end of the chromosome as the unit or element, it is shown that the six arms of the chromosomes of *D. melanogaster* retain their genetical identity in the remaining species. Within each element the sequence of the genes is dissimilar between the species, and it is shown that the different sequences of the genes in *D. melanogaster* and *D. pseudo-obscura* are not more alike than would result from chance. Few or no translocations have become established in these two sub-genera. A change in chromosome number would appear to occur by a special type of translocation within the heterochromatin area near the centromeres. This would more likely decrease chromosome number; hence *D. virilis*, in which the six elements are separate, is taken as the most primitive. The higher Diptera have six chromosomes. Whether these are identical with the Drosophila elements is unknown, but the integrity of the elements must break down in the more distantly related Diptera species.

Derivatives of Pentahydroxybenzene

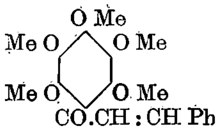
There has been an increasing interest in naturally occurring derivatives of pentahydroxybenzene, and these (calycopterin or thapsin, nobiletin, spinulosin, erianthin and pedicin and closely related compounds) are mentioned by W. Baker (*J. Chem. Soc.*, 662; 1941), who reviews recorded syntheses of pentahydroxybenzene derivatives and describes some very simple syntheses starting from pyrogallol, as a result of which, for the first time, some of these substances may now be very readily prepared. The pyrogallol was converted into 1 : 2 : 3 : 5-tetramethoxybenzene from which pentamethoxybenzene can be prepared by way of two intermediates. The synthetic methods make use in the final stage of the oxidation of *o*-hydroxytrimethoxyacetophenones by alkaline hydrogen peroxide to give dihydroxytrimethoxybenzenes. The catechol derivative is oxidized by aqueous ferric chloride to the quinone, various derivatives of which are described. The compound is oxidized by alkaline potassium persulphate to the pentahydroxyacetophenone derivative (II), from which the naturally occurring chalkone pedicellin (III) is synthesized. Pentamethoxybenzene, by the action of acetyl and aluminium chlorides in ether, gives hydroxypentamethoxy acetophenone, from which (see NATURE, Jan. 10, p. 52) hexamethoxybenzene can readily be obtained.



(I)

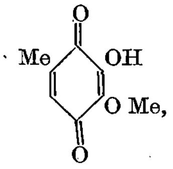


(II)



(III)

A synthesis of the mould metabolic product fumigatin, 3-hydroxy-4-methoxy-2 : 5-toluquinone,



a derivative of tetrahydroxybenzene, is also described by W. Baker and H. Raistrick (*J. Chem. Soc.*, 670; 1941).

Preparation of Deuterium Compounds

SOME experiments on the preparation of tetradeuteroethylene $D_2C : CD_2$ are described by C. L. Wilson and A. W. Wylie (*J. Chem. Soc.*, 598; 1941). This substance has been prepared before, for example, by introducing deuterium into the ethylene molecule by exchange in presence of a nickel or platinum catalyst and by the combination of deuteroacetylene and deuterium bromide under the influence of ultraviolet light, followed by the removal of bromine from the resulting dibromoethanes by zinc. The present authors find that a mixture of isomeric dibromotetradeuteroethanes containing about 10 per cent of ethylidene dibromide is formed by passing deuterium bromide (an apparatus for preparing which from bromine and electrolytic deuterium is described) and dideuteroacetylene over a prepared charcoal catalyst at 180°. The best sample contained 99·7 atom per cent of deuterium. The isotopic analysis was made by burning a mixture of the sample with highly purified ordinary ethylene dibromide by passing in a stream of dry air over red-hot copper oxide, purifying the combustion water, determining its density, and calculating the deuterium content by a formula. The reaction with zinc of the mixed deuterobromides in solution in purified dioxane to which one drop of deuterium oxide had been added was the method used for the preparation of tetradeuteroethylene, by reaction of which with bromine pure tetradeuteroethylene dibromide was obtained.

Comet Positions by Cross-bar Micrometer

W. T. HAY has described his home-made micrometer specially used for the determination of comet positions (*J. Brit. Astro. Assoc.*, 52, 1; 1941). The cross-bar micrometer consists of two metal wires (in the present case 10-amp. tinned copper fuse wire) set at an angle of 90° to one another and crossing in the middle of the field. A third wire bisects two of the right angles thus formed, and it is used for setting the micrometer in its correct position; this is attained by setting the third wire parallel to the celestial equator, so that a star will move along it when the telescope is moved in right ascension. When a comet and a star have been located in the same field, the driving clock of the telescope is stopped, allowing the two objects, which should be north and south of the field, to drift across the field of view. The difference between the mean of the times when the star crosses the wires, say, north of the field, and when the comet crosses the other two wires on the south of the field, gives the difference in right ascension in mean time seconds, which is then reduced to sidereal seconds. Half the sum of the times required by each object to cross its wires, reduced to sidereal seconds, multiplied by 15 times the cosine of the declination, gives the difference of declination in seconds of arc. In a separate paper Hay gives the results of nine observations of Comet van Gent, and from these Davidson and Sumner computed an orbit (see NATURE, **148**, 562; 1941) which is slightly hyperbolic.

Leander McCormick Proper Motions

A. ALI has published (*Mon. Not. Roy. Astro. Soc.*, **101**, 7; 1941) the result of the preliminary work done in connexion with the study of proper motions of the faint stars in the *Publications of the Leander McCormick Observatory*, 5, 11 (1937), on the basis of the two-streams theory. Three groups, which included about 2,100 stars, were selected sufficiently far apart from each other to give a fair idea of the preferential motions. As the form of the frequency curve was found to be very sensitive with regard to the position of the absolute origin in each region, three "absolute" origins were employed in each region, their respective frequency curves being obtained. A description is given of the method for determining the three absolute origins, and three figures show the frequency curves for Group 21 and Regions 276 and 295 included in it. The frequency curves, generally speaking, are distorted by considerable irregularities, and it is difficult to analyse them by Eddington's 'trial and error' method. Indeed, the absolute origin is indeterminate, indicating the presence of systematic or relatively large accidental errors, and it is suggested that a systematic error may exist in all the galactic regions in the McCormick memoir.

Interstellar Lines in the Laboratory

THREE sharp interstellar lines at 4232·6, 3957·7 and 3745·3 A., which had not hitherto been identified, have been reproduced by A. E. Douglas and G. Herzberg (*Astrophys. J.*, 94, 381; 1941) in a discharge through helium containing a trace of benzene vapour. They are the $R(0)$ lines of three bands, with heads at 4225·3, 3954·0 and 3743·4 A. respectively, each of which consists of three singlet branches corresponding to a $^1\Pi - {}^1\Sigma$ transition. The laboratory and interstellar wave-lengths are in agreement to 0·03 A. The only lines of these bands which would be expected in interstellar space are those coming from the lowest rotational level of the lower state, which are just the ones observed. Since the molecule BH has a $^1\Pi - {}^1\Sigma$ system with a (0,0) band in this region, and since the rotational constant in the lower state of the new bands is close to that for CH, the isoelectronic CH^+ is suggested as the emitter. This suggestion is strengthened by the fact that the other neutral and singly ionized hydrides of the second period of the periodic system are all well known except for three, which in any case cannot have singlet bands. The presence of CH^+ in interstellar space, as well as the neutral molecule CH discovered some months ago, seems thus to be established.

AN EXPERIMENT IN SOCIAL SCIENCE

THERE is a growing appreciation of the problem of the relation between management and labour : it is one which bristles with difficulties, in part because there is a lack of understanding on both sides and often, indeed, unwillingness to try to understand. As labour grows more and more independent, partly because of its political power, it becomes more necessary than ever to seek any and every means to promote such understanding, so that a factory can be run for the common weal, to give continuous remunerative employment to all connected with it, to give a fair return on the money invested in it, having regard to the risk, to set aside sufficient for depreciation and development so that the business may last for generations and not collapse exhausted in a few years like the wheat fields of the West after half a dozen crops.

If these prime essentials are agreed, then every worker, high or low, must actually earn, that is, produce goods of a value greater than his pay ; if he fail to do this, then he is a drag on the concern and must be removed or it will fail. The usual stupid remedy for bad times is to reduce wages ; a more scientific solution would be to increase the amount of work and cheapen the product, thereby making it more competitive and easier to sell. Unfortunately, the economics of bad and good times are more complex than the above simple basic principles, but none the less they are still largely applicable in most factories.

It is the task of management to see that every worker is able to earn more than his pay by adequate production, also that quality is maintained, research and development fostered, plant and machinery kept in order. Over and above this, good management has an even more important task based on the recognition that the workers are not herds but individuals with hopes and aspirations, people to lead rather than drive. In the old family concern the boss—"old Mr. Tom"—knew most of the work-people by their given names and something about their hobbies ; to-day this is much more difficult, especially when an overworked general manager has several thousands under him. Much can, however, be done, and it may be of interest to give an account of efforts made in a large factory employing both sexes some twenty-five years or more ago, largely before general interest was attracted to such questions.

The work is conveniently grouped under the headings of education, recreation, health ; we anticipated Hitler in devoting most of the efforts to the young people, remembering both that they are most impressionable and are continuously growing up.

Education. All young persons, as the Factory Act calls them, had to pass a certain standard before being taken on. The girls had to pass the top standard to qualify for the 'cleaner' work, for which there was always a long waiting list. The top standard was also required for the laboratory, to which a limited number were recruited each year after an interview by the chief chemist. The laboratory was regarded as the training ground for the staff. Everyone in it had to go to evening classes at the expense of the firm, at first in the home town and afterwards at the nearby city, to which travelling expenses were paid : some obtained external B.Sc. degrees in this way. (This was before the days of occasional day-time release which Dr. A. P. M. Fleming has since sponsored.)

At the end of the year the progress of each man was reviewed and a few 'square pegs' discharged. It was considered fairer to do this at the start than let them grow old in jobs for which they had little aptitude and probably less inclination. Such a system gives a larger number of recruits the chance of making good. Payment was by an age scale. The laboratory lads were encouraged in every way to take part and help in the social work and to develop any talent for organization or leadership. One got to know them well and to select those best fitted to be under-managers, alternatively research assistants. To-day some of them are managers in responsible positions.

On a smaller scale, the same progressive training was extended to the technical director's personal staff, which handled all works questions not pertaining to the actual processes. It was ripe for extension to the whole works, where any promising boy, generally discovered through the Scouts, was picked out and given a chance.

The advantage to the lads of this training is obvious : what the firm gained was a reservoir of men of all grades of ability available to fill gaps at home or abroad. We knew them and they knew our methods, a system which was infinitely more satisfactory than bringing in strangers.

Recreation. It is essential that the workers should manage their own affairs, but they need and welcome guidance in their organization. They do not want recreation arranged for them by a welfare staff. Our Girl Guides were highly successful, there was a waiting list to join them and a high standard of conduct was set ; here more than anywhere was there an opportunity of teaching the team spirit. The Boy Scouts were also popular, but the boy at this age very properly is more inclined to go his own way.

The company had provided a particularly fine recreation hall and canteen, including a theatre, which was the centre of a variety of activities all managed by the work-people and staff. The most interesting were the dances, sectional or large, which were self-supporting. These were visited by the technical director and certain members of the staff and their ladies—there was no formality or segregation. We were told our presence was desired and helped to make the affairs a success. I have no more pleasant recollection than the comparison of the dresses and general appearance of the girls at the beginning of these efforts and fifteen years later, and the young men had equally progressed. This social progress was in itself ample payment for much time devoted to this work—the girls made better marriages as one consequence of it. The credit was due in particular to the tact and general self-sacrifice of our lady manager, but it was personal also to a surprising extent, for on a change of management which withdrew the personal touch, the social functions languished and became less successful.

Interdepartmental games are a good method of fostering pride in the departments, and competitions for shields and cups, which are exhibited in the workshop all the year, do a lot of good in making workers feel they are part of a large family and not mere hands. The success of these, however, depends on a display of interest in them by the management ; they tend to die away if left to the players themselves.

We never found a means of really breaking down the barrier between works and office on the social side—a stupid distinction which in reality was non-existent—for the many offices in the works counted as works staff and played with us. Perhaps we did not try hard enough and left the office folk to find out what they were missing.

Health. The health of the worker should be a matter of concern to management. Quite apart from occupational diseases and epidemics, undue sickness in any one department is a sign that something is wrong and needs investigation. Departmental as well as general statistics should be reported. An undue amount of sickness among the girls led to the discovery that in order to get to work in time in the morning, many of them neglected to have a proper breakfast. A 40-minute-later start, that is, a 44- instead of a 48-hour week, was tried as an experiment, with an agreement on the part of the workers that they would try to maintain output and on ours that they would not lose pay. When things had settled down, it transpired that in the long run a slightly larger output was obtained and the sickness figure fell considerably. A watch on the sickness figure of small sections usually led to the discovery and rectification of the cause.

Many sections of the firm were working under conditions of limited floor space while new buildings were under way. Increased demand could not therefore be met by putting on extra girls, but only by higher production from the pieceworkers. To this end we made what are now called motion studies, an operation requiring the greatest tact. Varying rest periods, change of work so as to bring another set of muscles into play, height of seat and accessibility of components were all studied, with the result that we were satisfied that we did obtain the highest output per girl (paid for as piecework) that could be kept up day by day for a number of weeks. On one occasion the opportunity presented itself of working in circumstances in which the same girls, at their own wish, did even more, working for three days only per week. They kept this up for two weeks and then asked to give it up; the strain was too great and they found themselves tired for the rest of the week.

Overtime should be sparingly used for young persons; older men like it to provide a bonus for holiday occasions, but in the long run the same amount of work was done as if only normal hours had been worked.

Motion study under a special officer is to-day a regular practice, and much can be done to make the work easier. On the whole, operatives like monotony, something they can do with their fingers mechanically while they chatter and sing. They are suspicious of change unless they feel they have absolute confidence in the fair dealing of the management, and in particular a right of personal appeal to the top.

One of the most difficult things is to get hold of ideas from the workers to improve the process. There is the fear that the foreman will annex it as his own, or that if one goes past him that he will take it out of the individual. Suggestions boxes too often contain claims regarding alterations which the engineers already have in hand. The more management at the top knows the work-people, the easier it is to get a hint here and there where the shoe pinches, and to take equally quiet methods to put the trouble right.

Our wages were a few shillings above the local average, so that living on the same scale our peopl were just that amount better off. They were extraordinarily generous, as English working-people are giving freely to help fellow-workers in adversity an to causes sponsored by us which commended themselves. Perhaps I should say that all this wa largely before the advent of the cinema, which ha done so much to absorb the loose shillings from th people's pockets.

We were always seeking methods of giving extr benefits to the work-people, partly as a means o profit sharing, partly to shield them in adversity, an partly also with the hope of retaining our labour an not having constantly to take on new people. Thi aim was achieved, for our labour turnover was one o the lowest in Great Britain. We were early in th field in granting holidays with pay, depending onl on good time-keeping. We gave a weekly wag bonus for length of service. We started pension depending on the will of the board—non-contributor because any fund on an actuarial basis would hav been too costly. We postponed co-partnershi because of fluctuating profits—workmen do not lik the years in which no dividend is paid.

Perhaps our greatest success was group lif insurance—every man of long enough service wa given a policy for a year according in amount to hi standing and the report on his general proficiency. The minimum was £100, and many workers had twic this. The realization by the married man that i anything happened to him his wife and childre would receive what seemed a large sum—enough t start a small shop and keep them from want—had a profound effect on his well-being. The cost was considerable, but I am sure we should have been amply repaid.

Perhaps what has been said is enough to portray a restless management always seeking to make work happier for all and to better the lot of the worker both at work and at home. A loyal band of helpers found zest in the cause while our reward was close at hand. Needless to say we had no strikes, a very minimum of friction in spite of the fact that externally the years were very difficult ones, and a loyal response to any extra effort for which we asked.

The function of management *vis-à-vis* the worker is necessarily to drive, but when both sides understand each other, 'drive' becomes largely 'guide'.

PHYSICAL FEATURES OF COMET 1941*c* (DE KOCK)

R. H. STOY has described (*Mon. Not. Roy. Astro. Soc.*, **101**, 7; 1941) the chief physical features from an examination of 24 plates taken with the Cape astrographic refractor on 18 days between January 20 and March 6. The plates were projected on to a piece of paper with the aid of an enlarging lens and a 500-watt lantern, the main features of the comet being then sketched in. The orientation of the drawing and position angles were derived from the lines, the positions of which were known, and when these had been completed an attempt was made to match the outlines of the observed caps by known curves.

It is interesting to notice that in nearly every case it was possible to find a catenary that fitted satisfactorily. There was a remarkable similarity between the early appearance of this comet and Donati's Comet of 1858. Thus, Donati's Comet showed a dark division between the two principal tail streamers, and this feature was very pronounced in 1941*c*. The envelopes or caps were also very similar in both comets, and the shapes of most of these could be very satisfactorily represented by catenaries. In all these cases the departure from a catenary was in the sense that the observed curve was less divergent near its open end than was the catenary that fitted it best near its vertex.

This departure should indicate that the velocity of outflow from the nucleus of the matter forming these envelopes was steadily increasing, on the fountain theory of the formation of these caps, outlined by Eddington in *Mon. Not. Roy. Astro. Soc.*, **70**, 442 (1910). It is remarkable, however, that the linear size of the caps did not increase from day to day, as would be expected on the fountain theory, which indicates that the velocity of outflow from the nucleus of the matter forming the envelopes should steadily increase. From January 20 until 28, the date of perihelion, the inner caps grew brighter as they got smaller, but there is not the same amount of evidence available for the outer caps. What there is shows that these outer caps seem to have remained much about the same size, or in some cases to have expanded slightly before starting to contract.

A full description is given of the phenomena visible on the plates for each day when photographs were taken.

FIDDLER CRABS

JOCELYN CRANE has made important and interesting observations on these crabs ("Crabs of the Genus Uca from the West Coast of Central America." Eastern Pacific Expeditions of the New York Zoological Society. XXVI. *Zoologica*, 26, Part 3; Oct. 31, 1941). The present paper deals with specimens taken on the *Arcturus* Oceanographic Expedition (1925), on the Eastern Pacific *Zaca* Expedition (1937–1938) and on a special trip made to the Pacific shores of Panama by Miss Crane herself in January and February 1941.

The studies of habits and behaviour made on this last trip embrace a large amount of new knowledge on the ecology and especially the courtship display and mating of these crabs. Twenty-seven species are accurately described, eleven being new to science. There have been different opinions about the meaning of the waving of the large claw in fiddler crabs, but it is quite definitely established by these observations that this waving of the large claw, at any rate in the region investigated, is primarily for the attraction of the female, at least during the breeding season, and only secondarily for the warning off of crabs trespassing on a male's feeding range. This waving is only a part, or step, in a definite courtship display or dance which varies so greatly with the species that individuals can be recognized at a distance by their characteristic motions.

The patience which such studies necessitate is enormous, whole periods between tides being utilized and individual crabs kept under observation for many hours. The quality and quantity of the results show that such patience is amply rewarded, and Miss Crane is to be congratulated on the completion of a valuable contribution to the study of crab behaviour. Detailed colour notes are also given of all the crabs described; these colours vary enormously at the breeding season and at the time of display. "Courting adult males, in contrast to other adult males, and, of course, to females and young, change colour daily upon exposure to sunlight within the space of a short time—a few minutes to an hour or more being required. . . . That courtship coloration and display play a definite part in sexual recognition is certain, that they play one also in sexual selection is likely, but has not yet been proved by experiment."

A phylogenetic tree of the species dealt with is suggested and a key given to the species of Uca occurring on the west coast of America and in the Galapagos Islands.

NATIVE SUBSISTENCE ON THE AMERICAN CENTRAL PLAINS

IN a recent paper, W. R. Wedel dealt with man's battle against Nature in the great plains of Kansas and Nebraska (*Smithson. Misc. Coll.*, **101**, No. 3: "Environment and Native Subsistence Economics in the Central Great Plains". Publ. 3639. Pp. ii+29+5 plates. Washington, D.C.: Smithsonian Institution, 1941.) This region of widespread droughts, dust-storms, and consequent crop failures has been for some centuries the scene of attempted cultivation—sometimes successful, sometimes not. In view of recent failures the author has been collecting archæological evidence which tends to show that the aboriginal groups that exploited this region at various times and in various ways were themselves faced with similar adverse climatic conditions. In the western portion of this territory lies part of the High Plains province and immediately eastward of this is a stretch of sandy country now used for cattle rearing as the loose sandy soil renders it impracticable for agriculture on a large scale. Before the advent of the white man all this portion was roamed over by herds of bison, followed by nomadic tribes of Indians who preyed on them and on other abundant game. But farther east there is the great loess plain, fertile and well suited to agriculture and which was formerly inhabited by groups of Indians who cultivated the soil and made semi-permanent settlements. That these never became permanent was probably owing to the recurrent bad seasons—mainly droughts—that then, as now, might last for some years.

Archæological evidence goes to prove that groups of people did succeed at times in wresting a living even in the more inhospitable zones of the dry belt; as proved by sites containing the remains of charred corn and bone hoes, together with such quantities of animal bones as suggest that hunting was the main economy and horticulture a side line. In these circumstances the vagaries of the weather would play a less important part than in a wholly agricultural community. Droughts undoubtedly occurred in prehistoric times, the dust storms that accompanied them forming deposits over the sites.

In historic times great droughts occurred causing large population movements of the white settlers and reducing the Indians to the borderland of starvation. But it must be borne in mind that the old cultural patterns of the Indians were already broken by contact with the whites and they had not had sufficient time to re-adapt themselves. It is likely that in pre-white times they might have weathered these droughts as they were of comparatively short duration, although severe.

The author came to the conclusion that it is unlikely that any major climatic change has taken place in the central great plains within the last thousand years, and that alternate settlement and abandonment of this area was as true of primitive man as it is of white man's tenure when large-scale government aid has not come to his rescue.

EARTHQUAKE ORIGINS IN THE NEW ZEALAND REGION

R. C. HAYES, acting director of the Dominion Observatory, Wellington, New Zealand, has been investigating the origins of earthquakes in New Zealand ("Earthquake Origins in the New Zealand Region". Dominion Observatory Bulletin No. S.62). Using new material and improved methods, Hayes has redetermined the epicentres and depths of focus of several earthquakes in the New Zealand region for the years 1931 and 1936–40 inclusive, and has prepared a map showing these epicentres.

From these results it is evident that while the general distribution of earthquake epicentres does not differ appreciably from that indicated in earlier years, the more recent results bring out certain features which were not evident before. For example, the extensive seismic region, covering the eastern and southern parts of the North Island, Cook Strait area, and the northern part of the South Island is seen to have a sharply defined boundary on its north-west side, concave towards the north-west. It crosses the North Island from the Bay of Plenty to the region north of Cape Farewell, and there are very few earthquakes to the north-west of this line. Deep focus earthquakes may be significant.

Many of the shocks originating in the Gisborne – East Cape region and farther eastward have focal depths greater than normal. Origins at depths of 60 km. or more are common in the northern Hawke's Bay and Gisborne regions, the depths tending to increase up to about 100 km. for the submarine shocks farther eastward. Shocks originating in the south-west of South Island also have depths of focus of nearly 100 km. An isolated origin deeper than normal has been located near the north-eastern extremity of South Island (80 km.).

There is another zone, marked by origins at depths ranging up to 300 km. or more, which extends from near White Island in the Bay of Plenty to the region of Lake Taupo, a zone corresponding very closely with that in which volcanic activity occurs. The greatest depth of origin so far recorded in this zone is 320 km. (nearly 200 miles).

An important feature regarding the distribution of deep shocks which is indicated by the present results is their location with respect to the normal shocks in their vicinity. In most regions around the Pacific, deep-focus shocks tend to congregate away from the Pacific, the normal shocks being located on the Pacific side of them. This is clearly the case in the North Island of New Zealand, where the deep-focus zone has an extensive region of shallower or normal shocks to eastward of it.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public.)

Monday, February 2

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. B. A. Keen, F.R.S.: "Soil Physics, Theory and Practice" (Cantor Lectures, III).

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 3 p.m.—Dr. G. H. C. Hart: "Recent Development in the Netherlands Indies".

Wednesday, February 4

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. H. G. Jenkins: "Fluorescent Lighting".

Thursday, February 5

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. A. W. Ashby: "The Rise of Efficiency in Agriculture".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DISTRIBUTION ENGINEER to the Tees Valley Water Board—The Engineer and General Manager, Water Board Offices, Corporation Road, Middlesbrough (February 5).

CHIEF ELECTRICAL ENGINEER AND MANAGER of the Accrington Electricity Undertaking—The Town Clerk, Town Hall, Accrington (February 9).

SECRETARY-STEWARD IN THE DEPARTMENT OF PATHOLOGY AND BACTERIOLOGY—The Secretary, Welsh National School of Medicine, 10 The Parade, Cardiff (February 10).

HEADMASTER of the King Edward VII School for Boys, Lytham—Messrs. Wilson, Wright and Wilsons, Clerks to the Governors, 6 Chapel Street, Preston, Lancs. (February 13).

MAN OR WOMAN TO TEACH MATHEMATICS AND MECHANICAL DRAWING—The Principal and Organizer of Further Education in Rugby, 61 Clifton Road, Rugby.

ASSISTANT MASTER in the Technical School of the Royal Aircraft Establishment to teach Mathematics, Mechanics and Machine Drawing—The Central Register (ONC 745), Queen Anne's Chambers, London, S.W.1.

FUTURE OF THE CIVIL SERVICE

ALTHOUGH the Civil Service in Great Britain has received a considerable amount of criticism in recent months, the basic qualities and technique which have won for it the admiration of the world cannot be discarded without imperilling the execution of that new conception of government which should inspire policy to-day. To develop and modify rather than to destroy tradition and technique should be the object, and while Lord Stamp may have been right as to the unsuitability for higher administration of the exactly trained Civil servant, given to the analytical application of a legislative programme in a statute, co-operating with other departments similarly bound, and working to the elaboration of a complete static programme to be generally applicable by principle and precedent, this is not to say that his essential qualities are not required. Thoroughness ; accuracy of statement and precision of reasoning ; a proper respect for precedent ; the capacity to get quickly at the real gist of a situation and to set out the points briefly and lucidly ; the power of writing for public consumption, both vigorously and cautiously ; a strong dislike of muddle and irregularity in procedure ; a wide acquaintance with the machinery of government and a close acquaintance with two or three parts of it ; and a subconscious instinct for what can be said and done and what cannot—these characteristics will be valuable and essential whatever changes in organization and outlook are introduced.

The growth of the Service, and the struggles through which its tradition and strict code of conduct have developed, have been well set out by Emmeline W. Cohen in a recent work (see NATURE, Nov. 22, p. 601). Now Mr. H. E. Dale, himself a Civil servant with a distinguished career who retired in 1935, has given* an interpretation of the mind of those higher ranks of the Service who are primarily concerned with policy and are in immediate contact with Ministers. He limits himself to the conditions which existed up to September 1939, and within that qualification his admirably written book gives a very human picture of the life and work of the administrative class, more intimate, indeed, than that given in such biographies of Civil servants as Bernard M. Allen's "Sir Robert Morant" or Lady Murray's more recent "The Making of a Civil Servant". Indeed, this most readable volume should be as welcome to those considering the Civil Service as a career as it is relevant to the discussion of the place of the Service in the machinery of government to-day.

Mr. Dale attempts to describe and analyse, first the nature of the original human material from which the higher permanent official is recruited, and secondly the processes which have contributed to his making. Facts and opinions are kept clearly apart, and although it might be held that Mr. Dale is a little optimistic in holding that the Civil Service will emerge relatively little changed from the present struggle, and some of his conclusions are tinged with complacency, this does not detract from the merits of a really well-written book. The delineation of the positive merits of the Civil servant, which is the strongest feature of Mr. Dale's book, redresses to some extent the balance in controversies which have concentrated excessively on his weaknesses or deficiencies.

---

* The Higher Civil Service of Great Britain. By H. E. Dale. Pp. xiv+232. (London : Oxford University Press, 1941.) 10*s*. net.

The basic qualities and technical craftsmanship acquired as the Civil servant rises in the Service lead to a habit of mind or a conscious or subconscious creed. Compressed by Mr. Dale into five propositions, it is probably shared in some degree by most professional men, and it gives a clue to some of the real weaknesses of the Service. First, pure reason is not at present the most important factor in human affairs. Second, even in the realm of pure reason, there is much to be said for both sides on any complicated question which is fiercely disputed. Third, in a vast and highly organized society, great social, economic and political changes cannot be made quickly without arousing widespread opposition, much of it natural and reasonable, and without causing some unmerited suffering. Fourth, a minority which feels strongly and shouts loudly will often prevail both against the majority and the merits, unless the majority itself feels strongly. Fifth, in this complex and rapidly changing world, the strongest intellect and the keenest insight cannot predict anything like the full consequences of important decisions.

Such qualities of mind and outlook clearly favour the doctrines of moderation and prudence rather than opportunism. They are not necessarily inconsistent with the capacity to accept responsibility, although Mr. Dale more or less admits the tendency to leave well alone, and that preoccupation to keep a department out of trouble may influence conduct more powerfully than a desire to promote far-reaching projects. Indeed, when it is maintained that the Service takes power rather against its will and because otherwise the government of the country could not be carried on, Mr. Dale tacitly admits that the dislike of the Service for bureaucracy has not altogether prevented its expansion from being attended by a certain growth of evils associated with bureaucracy.

The evidence of Mr. Dale's book supports the central theme of a recent P E P broadsheet that the weakness of the Civil Service flows essentially from an obsolete conception of government as a regulatory, policing and taxing mechanism. Until a new conception of the function of government as the nation's instrument for planning, safeguarding and developing the collective inheritance and the social and economic welfare is recognized and adopted, with all the changes it involves in both the outlook and in the organization and methods of the Civil Service and its relations to Ministers, we are unlikely to secure the more constructive type of administrator, who sees opportunities and possibilities rather than difficulties and dangers, and possesses creative ability and the capacity for rapid and energetic action. That positive conception of administration and government is poles asunder from the retreat to individualism and chaos masked under Lord Perry's attack in "Beware Bureaucracy".

On the charges of lack of foresight and lack of knowledge of the new techniques of large-scale organization and management, or of science and scientific method or technique, Mr. Dale offers no evidence. He dismisses as pure nonsense the notion that the administrators despise or disregard the technical, and he maintains that the idea that in the ordinary office staffed entirely by Civil servants there is any habitual lack of co-ordination has no substantial basis of fact. On neither point is he convincing. The reports of the Select Committee on National Expenditure have provided disconcerting evidence of the existence of departmentalism, and there can be little doubt that the fuller use of the technical expert is one of the major future problems of the Service, and thought should be given to it immediately.

The picture Mr. Dale gives, however, scarcely supports the charge that the permanent Civil servant is out of touch with affairs, though the Post Office practice of insisting on provincial service as a preliminary to administrative work at headquarters could obviously be extended with advantage. Nor does it suggest that there is anything inherently opposed to such charges as are outlined in the P E P broadsheet, provided there is no shirking of the issues involved in disseminating throughout the Service a new outlook and new methods, and cutting out 'dead wood' where necessary. Much more than the two periods of long leave suggested by Mr. Dale will be required if the Civil servant is to adapt himself effectively to the new conception of government.

Much stress is laid on the changing relations of social rank between the high official and his Minister. The diminishing degree of homogeneity of the Service as compared with forty years ago is probably a more important and beneficial factor, but it is a matter of opinion whether the homogeneity of the main body of high officials, in spite of their individual differences, is really a source of strength to the Government, or to the public advantage.

A less beneficial change noted by Mr. Dale, as well as by Lord Perry, is the tendency for brilliant men to leave the Government service for employment outside it while in the prime of life. Dr. W. A. Robson has already stressed the need for greater mobility between the Service and the outside world, but in this drift from the Service the footsteps all point one way. Continuance of this tendency would be a serious matter, and when we couple with it the fact that the effect of the War of 1914–18 on the Higher Civil Service is about at its maximum, and that the effect will only disappear during the next decade or so, the comparative impoverishment of the Service can be readily understood. Such considerations support Sir Arthur Salter's argument for reinforcing the personnel of the Civil Service at the top with leading men in industry and science, and throughout its ranks with young men of energy and constructive ability—a policy to which Mr. Dale is firmly opposed for reasons which could equally well apply both ways.

In this detached but somewhat complacent picture of the upper six hundred in the Civil Service, there is evidence justifying the comment of *Planning* on the existence of chronic and avoidable overwork, frequently leading to breakdowns of health, not due to an excessive amount of work performed but to a failure to organize its performance. Such conditions lead readily to the lack of interest in and awareness of the technique of administration as a science, as well as to the absence of specialized services watching the working of the machine in relation to its current agenda and helping to keep it up to scratch in such matters as office organization, statistical methods, record-keeping and messenger services, and the failure to move the staff in accordance with changing demands. Very clearly we have as yet no thinking and planning organ free both from the immense pressure of day-to-day administration and from the intellectual tyranny of the departmental hierarchy and its departmental outlook, and at the same time in close enough relation with the responsible departments to keep it realistic and practical. The stress of war merely shows up limitations which were already becoming apparent in peace, and which are overdue for attention if the growth of the Civil Service is not to become a danger rather than a help to democratic government.

These problems of organization and of the adaptation of the Service to serve the increasingly complex needs of modern society are among the important tasks awaiting attention. A further problem is that of establishing such a relation between the Civil Service and the new semi-public services that there shall be no danger of a conflict between the two, or of a creeping back of abuses from which the Service was freed by strenuous efforts in the past. Both Emmeline Cohen and Mr. Dale, like Mr. T. H. O'Brien in "British Experiments in Public Ownership and Conrol", point to the dangers attendant on the great disparity between the salaries of highly placed Civil servants and those in control of these recently created bodies. In many ways, the responsibilities of these two groups are comparable, and steps should be taken to deal with the matter before an unfortunate precedent is established.

The first step must clearly be, as the P E P broadheet insists, the adoption of a new and positive conception of government. That is fundamental to the establishment of the organization and machinery for planning ahead, for adjusting continuously the working structure and technique of government to the problems with which it is called upon to deal, for overthrowing the domination of financial and accountancy considerations, for the neglect of scientific and technical advances and timidity in taking responsibility. Although the initial stimulus may come from without, the Civil servant should be grateful for the vidence which these recent sympathetic but balanced studies afford that, given the necessary measures of reform in personnel and organization, the main bulk of the Higher Civil Service will prove fully competent o grasp boldly and imaginatively the immense opporunities before them, and to discharge the more ositive functions demanded to-day without impairng the high traditions and code of conduct they nherit from the past.

PROTOZOOLOGY IN THE UNITED STATES

Protozoa in Biological Research

Edited by Gary N. Calkins and Francis M. Summers. Pp. xli+1148. (New York: Columbia University Press; London: Oxford University Press, 1941.) 66*s*. 6*d*. net.

SINCE the title of this heavy volume is somewhat vague—and its cost prohibitive, in present circumstances, to most British biologists—a brief description of its scope and contents will be more serviceable than a detailed criticism. The book actually contains twenty chapters of unequal length and quality, by as many American authors, dealing with a score of miscellaneous topics of more or less urgent interest to present-day protozoologists. According to the preface, the work is not a "textbook" on the Protozoa, but is intended "to stimulate further research on these unicellular animals".

Chapter i is entitled "General Considerations", and is by the senior editor. Chapter ii, by H. W. Beams and R. L. King, deals with some physical properties of protozoal protoplasm. Chapter iii, by R. F. MacLennan, summarizes recent work on cytoplasmic inclusions. C. V. Taylor discusses the fibrillar systems of ciliates in Chapter iv; and S. O. Mast deals with the motor responses of various protozoa in Chapter v. Chapters vi (on respiratory metabolism, by T. L. Jahn) and vii (on contractile vacuoles, by J. H. Weatherby) are also physiological. In Chapter viii G. W. Kidder—under an ambiguous title—describes some recent attempts to obtain bacteria-free cultures of Protozoa. Food-requirements and growth-factors in cultures are analysed by R. P. Hall in Chapter ix; while growth in general is discussed by O. W. Richards in Chapter x. C. A. Kofold then (Chapter xi) discourses on the "Life Cycle of the Protozoa". The four following chapters (xii–xv) are of genetical interest, and discuss fertilization (J. P. Turner), endomixis (L. L. Woodruff), sexuality (T. M. Sonneborn), and inheritance (H. S. Jennings). F. M. Summers next reviews some "morphogenetic problems" (Chapter xvi); and the volume concludes with four chapters (xvii–xx) on subjects of parasitological importance—pathogenicity (E. R. Becker), immunology (W. H. Taliaferro), host-parasite relationships (H. Kirby), and the parasites of the Protozoa themselves (by the same writer). The authors' names will afford sufficient indication of their present status in the protozoological firmament.

Each chapter is followed by a list of references, and there is a copious index at the end. There is also a lengthy "list of abbreviations" (of titles of journals cited) at the beginning (pp. xxvii–xli): but as these are mostly identical with those in the generally accepted "World List", the reason for their inclusion is not evident. It must be added that the get-up and printing are good, and few serious misprints have been detected. (On p. 449, however, "irradication"—for eradication—presumably reverses the author's intention.) The text is fully illustrated with 21 tables, 226 figures, and four half-tone plates. It is, in fact, what is commonly called "a mine of information" on the various subjects dealt with, and will undoubtedly be of great use to those who can refine the precious metal from the dross—a laborious and perhaps impossible task which the present authors can scarcely be said to have achieved everywhere.

With a few notable exceptions the articles are neither impartial reviews nor critical summaries of recent work—with full analyses of the international literature—but rather disquisitions on particular aspects of the various subjects which happen to interest the particular authors concerned. Much that is said is therefore to be found in earlier publications by the same writers, while much relevant research by others is ignored (or merely included, without discussion, in the appended references). Evidence may even be found, in more than one passage, that the "specialist" or "authority" is not himself always familiar at first hand with all the matters of which he treats. In general, American work is emphasized, and the pictures presented are thus not always complete or satisfying to a British worker in the same field. Two glaring instances will illustrate these points sufficiently. (1) The senior editor, in his introductory chapter, rehearses "some historical facts" about the Protozoa. Their discovery is here attributed to "Anton von Leeuwenhoek"—as it was in the same author's treatise of 1901. He thus appears to be still unaware that a vast amount of work has been done on Antony van Leeuwenhoek—especially in England and Holland—during the last forty years, so that there is no longer any excuse for germanizing his name or misquoting his words. Moreover, "Ludwig Hamm"—cited both in 1901 and in 1941 as the discoverer of the spermatozoa—is now a notorious ghost. (2) On p. 572 there is a figure of "the life cycle of *Endamœba coli* (= *Councilmania lafleuri*, Kofoid and Swezy, 1921)". But the real and very different life-history of *E. coli* is now known; and "*C. lafleuri*", as here depicted, is not recognized outside the author's own laboratory in California.

On matters of history, and on general biological principles, other authors also appear to be sometimes strangely misinformed. Moreover, their individual views are not always consistent; though this is to be expected, and perhaps welcomed. Yet it seems curious that not one of them appears to understand the interpretation of Protozoa as *non-cellular organisms*: so that while the editors (and some others) still regard them as "unicellular", we are told (on p. 578) that "it is biologically medieval to refer, as do many textbooks and other works, to *Paramecium* as a unicellular organism". Unfortunately, the writer then concludes that it must be "multicellular"—being unable, apparently, to appreciate the difference between cells and nuclei. For him the terms "multicellular" and "multinucleate" are seemingly synonymous. Such confusion of ideas may surely be called biologically prehistoric rather than medieval.

It would be easy to find fault with many another inconsistency in this book, and to criticize its lack of coherence and direction; for it appears to enunciate no new general principles, and scarcely succeeds—if that is its intention—in correlating recent research on the Protozoa with general biological concepts. Yet for my part I am grateful to my American colleagues, both old and young, for stating—or restating—their own views; and, with other British protozoologists, I envy them their ability to spread themselves so lavishly and unconcernedly in these difficult and disturbing days. All the same, I doubt whether this kind of publication will encourage further research of any real value—the one thing we all have at heart. I can only hope that my own misgivings are unjustified, and that other workers—younger and better and less constrained—may find inspiration where I have sought it in vain.

Clifford Dobell.

FORMULÆ AND TABLES FOR THE BOTANICAL LABORATORY

Plant Science Formulæ

A Reference Book for Plant Science Laboratorie (including Bacteriology). By Prof. R. C. McLean an Dr. W. R. Ivimey Cook. Pp. vii+203. (London Macmillan and Co., Ltd., 1941.) 7*s.* 6*d.* net.

IN botanical laboratories each individual worke tends to introduce modifications of methods o fixation, staining, etc., according to the particula requirements of his material and investigation; th result of this is that descriptions of methods becom so multiplied as to be very confusing to an occasiona worker in that branch of the subject, and much tim may be wasted in looking up and deciding betwee the many possible methods of carrying out any on procedure. In course of time most workers tend t collect their own card index of selected methods an the authors state that this book is in fact their car index put into a more convenient form. For specialized methods the index will still be required, but i "Plant Science Formulæ" may be found the receipts in the generally accepted form, of the commonly use fixatives, stains, culture media, etc., given in th *simplest form and with the minimum of inessentia* detail. It is inevitable in such a book that an specialist worker is liable to find certain method omitted or differing from those he is accustomed t use, and for this reason blank pages are inserted a the end of each section for additions.

As the authors point out, this is essentially a boo to have at hand in the laboratory and would los much of its purpose if put away on the library shel The receipts for technique are followed by sections o the various necessary accompaniments of laborator work, either of the laboratory steward, researc worker or teacher, as, for example, information o photographic work and preparation of lantern slide and museum specimens, odds and ends of informatio for the workshop, tables of weights and measure atomic weights, various physical formulæ and constants and logarithm tables, so that the author have made a very real attempt to collect into on book all the miscellaneous facts and formulæ whic are continually being required in the laboratory an are scarcely ever readily available.

The authors stress the point that the aim of th book is also to help the teacher who commences wor in a school or technical institution with nothing mor than the usual college training in the use of certai methods with reagents supplied ready prepared. I is hoped that such students have had sufficien training to enable them to make up reagents, cultu media, etc., given the receipts and sufficient dire tions, and to such as these, who also often have litt access to books and little time for searching ou directions, this book should prove extremely usefu For this class of reader there are also included lists the general requirements for the laboratory and th addresses of suitable firms who supply chemical microscopes and biological materials.

In some cases reference to sources of the metho would have proved useful for further details as t methods, but probably the book in its present si and price will meet a wider need than a larger an more expensive volume. The book will certainl prove of very considerable value if used, as th authors intend, essentially as a laboratory book t which constant reference may be made.

ANALYSIS OF FOODS

Food Analysis

Typical Methods and the Interpretation of Results. By Prof. A. G. Woodman. (International Chemical Series.) Fourth edition. Pp. xii+607. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 28*s*.

THIS is the fourth edition of a work originally published in 1915, and the declared intention of the author was then, and still remains, to provide a guide to students of analytical chemistry as applied to foodstuffs. A casual inspection of the contents at first suggested that there were some surprising omissions, but such criticism is promptly disarmed by the author who explains that his method was to select certain typical foods only, and to treat them at considerable length, so as to present the student with examples of the technique of food analysis rather than to cater for the requirements of the practising chemist.

While these intentions have been very ably carried out, it nevertheless seems to the reviewer that some of the material could usefully have been treated less generously, so that common foods such as cheese or dried milk might have received at least a mention; and that in six hundred pages devoted to food analysis, even if only for students, the word 'vitamin' deserves a place.

The first three chapters deal respectively with general methods of examination both physical and chemical, food microscopy, and colours and preservatives; here, as indeed throughout the book, the theoretical considerations involved in the various methods described receive adequate and capable treatment. One might query the statement concerning the presence of sulphurous acid and sulphites in foodstuffs that "there is no simple reliable qualitative test".

The section devoted to milk is fairly complete and up to date; the names of Gerber and Werner-Schmidt do not occur and one notices that the average fat content in the United States is apparently higher than in Great Britain (4·0 as compared with 3·7).

The general discussion of the examination of edible fats and oils, as well as that of the selected examples, namely olive oil and butter, is excellently written; it was noted that no mention is made of peroxide value. As with each of the typical foods dealt with throughout the book, the important question of the interpretation of results is carefully considered; this subject is often badly neglected, as more than one examination candidate has found to his cost.

Following a comprehensive description of the methods in common use for the analysis of carbohydrate foods, with particular attention being devoted to sugars and certain chosen foods, the remainder of the book deals with spices, cider vinegar, flavouring extracts and alcoholic beverages, more than one sixth of the whole book being allotted to the last-mentioned subject.

Woodman is very 'readable', and his book, in which no typographical errors were detected, is much less obviously American than most scientific publications from across the Atlantic. While many of the diagrams and tables have a familiar appearance, their source is invariably indicated with due acknowledgment. Very full references are given in footnotes and at the end of each chapter a list of books is given to which the attention of the student is directed for further study.

A. F. Lerrigo.

MATHEMATICAL REQUIREMENTS FOR STATISTICS

Statistical Procedures and their Mathematical Bases

By Dr. Charles C. Peters and Prof. Walter R. van Voorhis. Pp. xiii+516. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 31*s*. 6*d*.

THIS book is the outcome of a serious attempt to derive accepted statistical methods and formulæ from elementary mathematics. It opens with a chapter called "A Little Calculus"; and it may be presumed that the mathematical proficiency of the reader marches *pari passu* with his reading of the book, for the later chapters are on such subjects as partial and multiple correlation, the normal curve, non-linear correlation, analysis of variance, curve fitting and so on.

The point of view of the authors is easily comprehensible, and merits sympathy. On one hand we have books such as R. A. Fisher's "Statistical Methods for Research Workers", which promulgate formulæ and procedure by the voice of authority, without descending to proofs; on the other we have few text-books, but a profusion of memoirs, not only abstrusely mathematical, but often controversial. A student or researcher, initially of slender mathematical equipment and desirous of applying statistical methods to some problem of research, may well feel at a loss. This book is intended to help him, and without doubt, by the time he has read its almost five hundred pages (the last thirty are devoted to useful tables) he will know a great deal about questions of distribution, correlation, regression, the χ^2-test and the rest. Will he be able to digest his knowledge and discriminate?

While fully sympathetic, one may feel dubious about the efficacy, and even the desirability, of such an approach. Envisage a continuous variate; the compound probability of even two individuals involves a double integral, and n-fold integrals with very large n are the merest commonplace. Consider again the question of partial correlation; the abstract underlying ideas are those of linear transformations and positive definite quadratic forms. Indeed not only the infinitesimal calculus, but also algebra, both matrix and combinatory, and some notion of the geometry of hyperspace are prerequisite to the study of statistics. It is better that these fundamental preliminaries should be mastered as if for their own sake. Then, when the time comes for application to mathematical statistics, one will have a background not merely for understanding and applying, but also for doubting and reserving an opinion; for high authority does not yet speak with a single voice.

A truly elementary and comprehensive book of this kind would have had to be at least twice as long again. For example, the normal function is deduced from the exceedingly special case, the symmetrical binomial; while the χ^2-distribution and many other results are only incompletely established, the reader being referred to more advanced treatments.

THE GENETICS OF SPECIATION

Genetics and the Origin of Species

By Prof. Theodosius Dobzhansky. Second edition, revised. Pp. xviii+446. (New York: Columbia University Press; London: Oxford University Press, 1941.) 28*s*. net.

DURING the last ten years geneticists have been getting to grips with the problems of evolutionary change; Prof. Dobzhansky describes the results of their work in this book. The first edition appeared in 1937, and it was reprinted two years later; but a second edition became necessary in 1941. These facts show clearly the great need for a book of this type. They also show how well Prof. Dobzhansky has filled that need.

Substantial additions have been made in the second edition, including one new chapter on "Patterns of Evolution", and reference is made to many original articles which have appeared since 1937. As before, one of the outstanding features of the book is the wealth of Russian material made available in English for the first time.

Genetics occupies a rather special place in experimental biology as it has always been concerned to a great extent with groups of individuals; indeed the laws of inheritance are most commonly used to define the statistical properties of such groups. This is, however, largely a reflection of genetical methodology since the older study of inheritance is at root the study of gene transmission from individual to individual and of gene action within the individual. Such a statement cannot be made about the newer development of population genetics. It is true to say that the genetical behaviour of a population depends ultimately on the behaviour of each constituent individual, but a new level of integration is reached because the population can have properties not possessed by, and not always directly predictable from, the individual. The emphasis which Prof. Dobzhansky lays on this point is not the least of the services which he has rendered to the genetical study of evolution.

In proceeding to investigate these special properties of populations two main lines of approach have been used, each of which is itself composite. In the first place there is the genetical and cytological analysis of samples taken in the wild, from which conclusions may be drawn regarding the genetical structure of the population and by means of which its behaviour may be compared with that of other populations related both in time and in space. Secondly, there is the attempt to infer the behaviour of groups of organisms from the known properties of single individuals. In both of these approaches genetics, cytology and statistical mathematics have played their parts in the past, and the ultimate understanding of population behaviour and of evolution depends on the successful combination of these various weapons in the future attack on the problems involved. Prof. Dobzhansky performs his second great service in bringing together the evidence which has already accrued in the different ways, in pointing out the conclusions to which this evidence leads and, perhaps most important of all, in exposing the deficiencies in our knowledge, while formulating working hypotheses which should help in guiding future attempts to fill these gaps.

If criticisms are levelled at the book, the most important will perhaps be that the advance on the older genetics is not greater. In following out the mechanism of inheritance, genes giving striking and easily identifiable effects were used of necessity; but in Nature one is concerned much more with those characters which depend on the combined action of many genes each having a relatively small effect on the phenotype. Species differences are polygenic, and just as the progress from individuals to populations involves a new integration, the properties and behaviour of polygenic characters are distinct from those of the so-called qualitative type used in the older genetical studies. It must, however, be said that Dobzhansky could have done little beyond directing attention to the necessity for a study of polygenic inheritance, for up to the present few investigations of this kind have been made.

A further point should be mentioned. The effect of population size on the spread and fixation of genes is discussed at some length, but it is not made clear that, inasmuch as the mating system, which may favour inbreeding or outbreeding of any degree of rigour, is always subject to genetical control of greater or less precision, the effective size of the population is itself a character on which selection will act and hence is adaptive. This must clearly have a profound influence on the interpretation which one places on the results of variation in apparent population size. Indeed, the whole notion of population size is rather vague unless a detailed knowledge of the breeding system is available.

The phraseology will seem to many to be somewhat unusual in a few places. In particular two mistakes, namely, the use of "indefinitely large" for "infinitely large" and the reference to the somatic number of chromosomes in polyploid wheat as the diploid number, are regrettable, because both are common errors which may have an extended life as a result of their unfortunate use in a book of such authority. These and their like are, however, minor blemishes and should cause the reader little trouble. "Genetics and the Origin of Species" is strongly to be recommended to all who, whether geneticists or not, wish to know how genetics can help in understanding evolution, and the extent to which it has already been used for this purpose. K. MATHER.

PSYCHOLOGY OF EVACUATION

The Cambridge Evacuation Survey

A Wartime Study in Social Welfare and Education. Edited by Susan Isaacs, with the co-operation of Sibyl Clement Brown and Robert H. Thouless. Written by Georgina Bathurst, Sibyl Clement Brown, John Bowlby, G. A. Bullen, Nancy Fairbairn, Susan Isaacs, N. S. Mercer, Madeline Rooff, R. H. Thouless. (Contributions to Modern Education.) Pp. ix+236. (London: Methuen and Co., Ltd., 1941.) 8*s*. 6*d*. net.

THIS book deals too compactly with too much detail to admit of any adequate summary within the limits of a review. To stress some of the implications of its title: it contains the findings of a team of experts, who, in organized co-operation, applied their special techniques of investigation to a local group of evacuated London children. The population under examination was therefore necessarily limited (though actually considerable in number), and the results, as the book makes clear, must not be too readily generalized. Yet the group was probably typical of the whole. It is beyond doubt that a study so careful and detailed as this of a relatively small and selected sample of the army of evacuees has more scientific value than a superficial description of a greater number of children, and the contributors have earned the gratitude of students in many fields by the promptness with which they seized the opportunity which was presented to them.

Few centres were so fortunate as Cambridge in finding such a varied team of experienced research workers at hand. Their methods are described in adequate detail. In the main they relied on a combination of statistical analysis and case histories. The statistical material, presented with the competence one expects from Dr. Thouless, is subjected throughout to qualitative examination. The general problem is studied from many angles, and all concerned, including the children themselves, are allowed to present their views. Relations in the reception homes, recreation, economic factors, the reasons for the regrettable drift back to London, and the teachers' own problems are among the topics studied. The return to London was already taking place before the inquiry could be initiated, yet even this fact was turned to account, for parallel inquiries were made in the London areas concerned in order to determine the causes of the partial failure of evacuation. That the picture presented is familiar in its outlines does not diminish the value of the book, for it is of the first importance that general impressions should be checked by careful research. Some popular opinions are shown to be based on exaggerations, as when it is found that the proportion of maladjustments in the foster homes is only about 8 per cent, not a high figure in the circumstances. An interesting point is the suggestion that such difficulties increase with the age of the children. In early adolescence problem situations are not unusual in the home, and the stresses of growing up into independent personalities are exacerbated when the child is placed with strangers, among whom the easy tolerance of the home is inevitably lacking.

A full year had been allowed for working out the scheme of evacuation, and the time was largely wasted. The difficulties were immense (and their scale can be seen more clearly now than before evacuation) but surely there could have been less 'trial and error' procedure. The actual movement of the child population was effected with efficiency, but too little thought had been given to the difficulties to be encountered in the reception areas, and the outstanding failure was in respect to psychology. A great deal is now known about children, and the accumulated experience of child guidance clinics is available to meet the problems arising from such a profound mental disturbance as that caused by separation from parents under the threat of air attack. If a mass movement was to be successful it had to be soundly based on the psychology of children and parents. This was neglected. It is clear, for example, that the responsible authorities either under-estimated the strength of parental affection, or over-estimated parental self-control. Insufficient regard was directed to the emotional unity of the family, and as little to its economic unity. A total family income cannot be considered as distributed at so much per head. Every working-class mother knows this: authority apparently did not. To take one point only, when the children of a family are scattered the normal 'handing down' of clothes becomes next to impossible, and a new expense is thrown upon the parents' limited resources.

Clinical psychologists are well acquainted with the emotional disturbances which originate in a sense of the insecurity which accompanies dependence. We have learned that the benefits of adoption into a thoroughly good home have to be balanced against the child's unhappy realization that others may dispose of him like a parcel of grocery, and that he is powerless to resist. This was the situation of the evacuated child, with the added terrors, whether real or imaginary, of the War. Difficulties from this source were unavoidable: they should have been expected, and measures taken to reduce their effects. Fortunately, the average child is a resilient creature, or evacuation would have been even less successful. The difficulties of the foster parent also might have been envisaged. What *is* the uninformed householder supposed to do when called upon to take charge of a border-line deficient ?

The authors are content to state the facts they found, with just a little censure, much praise, and no polemics. The book is an important contribution to the literature of psychology and sociology, and deserves high praise. The style is attractive, the argument cautious and restrained. Its value can be more than historical, for not only is evacuation a continuing problem, but there will also be subsequent questions of re-settlement of a similar kind. The nation is conducting its greatest sociological experiment and the book under review is an analysis of part of the data. Other studies would be welcome if carried through as well as this. Then will come the practical task of convincing the authorities that psychological principles must provide the bases of all attempts to handle human beings. There is as yet little evidence that they are willing to learn a lesson so inconvenient to routine administration.

A. W. WOLTERS.

CHEMICAL WARFARE

Chemical Warfare

By Curt Wachtel. Pp. ix+312. (London: Chapman and Hall, Ltd., 1941.) 24*s*. net.

DR. CURT WACHTEL organized the pharmacological section of the Kaiser Wilhelm Institute during the War of 1914–18. He was intimately concerned in the investigations which led to the very successful use of chemical weapons by the Germans, and has kept his notebooks, which contain descriptions of many experiments still unpublished. After the War, he studied the hazards due to toxic gases in peace-time in Germany, Russia and elsewhere. He now lives in the United States, and has written a book on chemical warfare which he hopes will help the military of his adopted country. The book was published in the United States by the Chemical Publishing Company and an English edition has now appeared.

Many aspects of chemical warfare are briefly discussed. The history of the subject from the time of the Pharaohs is reviewed. The circumstances which led to the development of chemical warfare in Germany during 1914–18 are described with interesting details about the personalities involved, and a picture is drawn of an ideally efficient institute for the advancement of knowledge in this field. The author does not hide his belief that German men of science are more gifted than those from other countries, and that Fritz Haber was the greatest of them all. He is fond of speculating on what might have happened had circumstances been different, and the main circumstance to which he attributes Germany's defeat is the selfishness of second-rate bureaucrats, who would not listen to their technical advisers. This theme recurs and tends to irritate the reader by spreading an atmosphere of grievance over the book. The author hopes to aid the unimaginative bureaucrats of to-day by putting ideas in their heads, but the ideas are only vaguely put forward, and must have occurred to anyone who has given serious thought to the matter. There is no evidence that it would be possible to put them into practice.

The results of a number of German investigations are now published for the first time, but without those corroborative details which alone can carry scientific conviction. Indeed, there are so many obvious minor errors that it is impossible to know whether any particular statement is reliable or not. Misprints, of which there are many, are easily detected when they only involve single letters, but apt to be confusing when, for example, it is said that cyanogen chloride is heavier than cyanogen chloride, or when the same formula is given for both phosgene and diphosgene. There are faults in the English, such as when "tearing" is used to denote the shedding of tears. Concentrations of gas are usually given in milligrams per cubic metre only, but on p. 195 they are also given in cubic millimetres per cubic metre, and the two sets of figures cannot both be correct. This fact casts doubt on the other figures in the book.

It is hoped that Dr. Wachtel will be able to give the scientific and military men of his adopted country more direct help than they will get by reading this book, which has too many facts for a popular book and too few for a scientific book.

CANADIAN NATURAL HISTORY

A Naturalist in Canada

By Dan McCowan. Pp. xii+284+20 plates. (Toronto: The Macmillan Company of Canada, Ltd., 1941.) 15*s*. net.

THE author of the book under review displays more than a speaking acquaintance with the natural history of both the Old and the New Worlds. Since his boyhood days in Scotland, Mr. McCowan has been an ardent student of Nature in the field, and his migration to Canada many years ago merely served to intensify his curiosity concerning the why and wherefore of all things animate and inanimate. He is no armchair naturalist.

A brief glance at the subject-index immediately serves to acquaint the reader with the diversity of the subjects discussed by the author, which are distributed through thirty-nine chapters and embrace such widely divergent topics as the preparation and uses of pemmican, the status of the oolachan or candle fish, the economic importance of the whitefish of Canada's inland lakes, the breeding and blood-sucking habits of the vexatious and persistent northern mosquitoes or "animated gimlets", the ways of eagles and other rapacious birds, and the secluded man-avoiding habits of the isolationist colonies of the white pelican. Other interesting chapters are devoted in whole or in part to the edibility of wild plants, the chorus of frogs which contributes in no small measure to the reality of the Canadian spring, and the habits and conservation of Canada's wild ungulates including the musk-ox, moose and Rocky Mountain goat as well as the reduced populations of the pronghorn antelope and buffalo, now protected in special reservations as wards of the Government of Canada.

No account of Canada's natural history resources would be complete without mention of the rich Dinosaur beds of the Red Deer River valley at Drumheller, Alberta, and the fossil rock libraries of the Rockies; so, due attention is paid to those in a special chapter entitled "The Record of the Rocks".

As for the plan of the book, the marked lack of an ordered sequence in the arrangement of the chapters is explained by the fact that each represents a separate and distinct unit prepared for presentation in a series of broadcasts to Canadian listeners. Thus the circumstances which inspired the book may serve to explain the double standard of diction employed by the author. At times, for the sake of expressiveness, the author does not despise the use of modern trite expressions, while at other times he proves himself equally facile in welding the beauty of words to the beautiful things of Nature. As an example of the former the reader is referred to p. 77, where the author, in stressing the importance of the house-fly, as a vector of disease conveys his meaning in the following words: "Many kinds of germs thumb a ride in the hairy coat of the fly and thus are enabled to make a happy landing in places where unscreened meat or other human food is exposed." As an example of the latter the reader is referred to the following passage on pp. 270–271: "The times may be out of joint and the world of men all awry, but in the woods and fields and on the lone moorlands the flowers and the bees contrive to work together harmoniously and in peace. They are not vexed by the rattle of sabres nor by the ceaseless clang of the armourer's anvil. Overhead are blue skies and white clouds, morning sunshine sparkles on the rippling lake and clear-running stream: the leafy trees cast a grateful shadow at noon. When evening falls there is dew on the meadows and a great hush in the green forest."

In these days of modern ecological methods where the behaviour of species is measured with a yard-stick, their reactions resolved in the columns of lengthy tables and reduced to graphical representation, it is refreshing to pick up a book in which the author, imbued with the sheer joy of his subject, looks at Nature clear and whole and not as so many separate pieces of a picture puzzle.

To those of us who have had the privilege of observing and studying Nature on both sides of the Atlantic, Mr. McCowan's book strikes a responsive chord and serves to recall many memorable days spent in collecting and research in the vast open spaces of the Canadian West, where often for company there was naught but the boom of the bittern among the reeds, the laughter of the loon on the lake, the bark of the coyote in the grove or the splash of the musk rat in the slough. Even solitude had its enchantment.

A. E. CAMERON.

Visibility in Meteorology

The Theory and Practice of the Measurement of the Visual Range. By W. E. Knowles Middleton. Second edition, completely revised and enlarged. Pp. x+165. (Toronto: University of Toronto Press; London: Oxford University Press, 1941.) 15*s*. 6*d*. net.

A SECOND edition of this book has been undertaken because of the large amount of work, both practical and theoretical, that has been done in the six years that have elapsed since the first edition appeared. This subject gains increasing importance as the rapidity of transport by sea, land and air continues to increase. The further developments of the subject in these six years appear to have induced a pessimistic outlook about it in the author, whose enthusiasm for the use of the visual range as a synoptic element, which in his opinion has been shared by no one else, appears to have evaporated at the same time that he has "abandoned the search for a rational scale of visual ranges". One of the aims of the researches that are reviewed in this book is, as is pointed out in the introduction, to quote again the author's words, "to separate the subjective from the objective aspects of the problem, the psychological from the physical, the accidents of what there is to look at from the meteorologically significant properties of the portion of the atmosphere through which we look". This aim the author keeps constantly before him in this book, as only in this way does there appear to be any chance of getting the subject simplified and clarified and set on a firm scientific basis, after which the development of standard instruments and the co-ordination of observational methods should soon follow.

E. V. NEWNHAM.

Spectra of Long-Period Variable Stars

(Astrophysical Monographs sponsored by the *Astrophysical Journal*.) By Paul W. Merrill. Pp. ix+107+7 plates. (Chicago: University of Chicago Press; Cambridge: At the University Press, 1940.) 15*s*. net.

OUR knowledge of long-period stellar variability is still so fragmentary that much of the available information is widely scattered throughout various periodicals, and many of the proposed hypotheses are without doubt destined to eventual rejection. At this stage such a monograph as this is doubly welcome, since the author presents and coordinates a wealth of observed facts regarding the spectra of these stars while carefully avoiding a too close identification of these facts with current theory. Valuable as photometric and spectrophotometric studies of these stars are, the most fruitful line of attack on the many problems they present is that of detailed spectrum analysis. Accordingly Dr. Merrill gives a general account of the lines and bands in characteristic spectra at maximum light, and goes on to trace their variation with phase. Afterwards he devotes a chapter to individual variables which have been made the subject of specially detailed investigation. Finally, he gives an admirable summary of the various hypotheses which have been advanced to account for the behaviour of these objects, and suggests the most fruitful lines of future research. Not the least valuable feature of the book is the series of seven plates in which the characteristics of the spectra are illustrated by excellently reproduced high-dispersion spectrograms.

Cine-Biology

By J. V. Durden, Mary Field and F. Percy Smith. (Pelican Books, A85.) Pp. 128+32 plates. (Harmondsworth, Middx.; New York: Penguin Books, Ltd., 1941.) 6*d*. net.

THIS little book is extraordinarily good value although written in popular rather than truly scientific vein. The trinity of authors of various training and callings have collaborated most successfully in producing a vivid and usually accurate account of the structure and life-histories of selected animals from Amœba up to and including the Insecta, and this account is well illustrated by numerous drawings and photographs. In spite of the title the last are, perhaps, less of a feature of the book than the 'photographic' clarity of most of the descriptions, which may accordingly be recommended to the youthful or would-be zoologist as well as to any intelligent layman. The whole is attractively and indeed charmingly written, with a minimum of technicalities and a useful glossary at the end; but the title is misleading in that only one prong from the fork of life is dealt with, and that is the one the very existence of which depends upon plants.

N. P.

This Physical World

A College Course in Science. By Prof. C. C. Clark, C. A. Johnson and Lt.-Comdr. L. M. Cockaday. Pp. x+528. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 22*s*. 6*d*.

AMERICA seems ahead of Great Britain in realizing the necessity of inculcating a nodding acquaintance of scientific method in those whose later activities in life are to be other than scientific or technical. The present volume is a re-written cultural course for those not pursuing science as a major subject. The result is a very attractive review of present-day scientific background, bringing home the benefits, and otherwise, of applied science and the fundamentals whence it springs. The first chapter properly outlines the scientific method, noting its historical growth and force in ascertaining the material truth of things, its demand for precision in measurement and integrity in interpretation. The review of basic knowledge and its consequences then ranges from contemplation of the heavens, the structure of matter, reactions among chemical elements, heat and heat-engines, waves, electrons, and modern electrical communications. The authors are out to impress the reader, with an easy, but accurate, style with the best possible illustrations, that science and its applications are mighty forces in our present civilization, and why not?

L. E. C. H.

GLACIATION AND SUBMARINE VALLEYS*

By PROF. REGINALD A. DALY
Harvard University

CONTINENTAL terraces are huge submerged benches, each surfaced by a continental shelf and a continental slope. The fall-off of shelf to slope begins not far from the 50-fathom isobath. The shelves vary in width from a few miles to 150 miles, their seaward gradient averaging about 1 in 1,500. The average gradient of the continental slope, measured from the fall-off to the flat plain of the deep ocean, is about 1 in 15, or 100 times as steep; measured from the fall-off to the 500 fathom isobath, the seaward gradient averages about 1 in 10, or 150 times as steep as that of the shelf.

Direct sampling shows the surface of the terrace to be underlain by loose, land-derived sediments, though exceptionally considerable patches of hard rock, without sedimentary cover, have been demonstrated.

With total length of 60,000 miles and average width of 100 miles, the terrace borders each of the big masses of land. Here we have that part of the sea floor which has liveliest interest for fisherman, navigator, and cable-layer, and therefore vitally relates to the practical life of civilized man. But the continental terrace has in addition a special scientific appeal, for its study has recently led to an astonishing discovery—the systematic ruggedness of its long outer slope.

It is already clear that the ruggedness is the result of dissection, intaglio carving, of the continental slopes by running water. The specific question is as to the nature of the eroding streams. Closely related is the question as to the time when the sculpturing took place.

Five years ago, I offered a hypothetical explanation of this mighty sculpturing of the continental terraces. Since then, new facts have been discovered and these seem to fortify the explanation. According to the preferred theory, the furrowing of the flanks of the continents was due to silty underflows—bottom currents of heavy water that rushed down the continental slopes, much as gushes of rain water 'gully' hillsides on the land. The water was heavy because laden with mud and sand in suspension, the mud and sand being made of rock particles which were two to three times as dense as clean sea water. The mud and sand were brought into suspension during the tumult of storm waves that broke on the shallows of the continental shelf, and during the rushes of the turbulent tides across the shelf. This weighted water crept slowly down the gently inclined shelf and then hurried down the much steeper continental slope. The velocity of these underflows is thought to have been so great that deep canyons and furrows were cut in the original sediments of the continental slope, and as many ridges were left between the new valleys.

Such trenching may be possible at the present time, especially where the zone of intense wave-action is only a short distance from the fall-off to the continental slope, but, according to the preferred theory, the furrowing of the slope was due to the special conditions of the Glacial Period, when there were drastic, world-wide migrations of the zone of breakers out to the edge of the continental shelf and back again.

Let us look first at the known facts and then at different hypotheses so far offered in explanation.

Observations of Submarine Valleys

Early in the latter half of the nineteenth century, it was shown that the generally smooth surfaces of the continental shelves flanking North America, Europe, and Africa are interrupted by trenches or 'channels', each of which begins a few miles from the shore and continues in a fairly straight line across the shelf, all the way to the fall-off where the continental slope begins, about 300 ft. below sea-level. At the fall-off the 'channel' merges into a 'canyon' cut in the continental slope. Here the widths of the valley-like trenches are measurable in miles, while their floors lie thousands of feet below the general surface of the continental slope. An example is the Hudson canyon, continuing the Hudson 'channel', which crosses the shelf and is itself *en axe* with the Hudson River at New York City. A few years of echo or sonic sounding increased the number of known canyons from a half-dozen to more than one hundred. This is already a large number, though less than one per cent of the total 'longshore length of shelf and slope has been adequately sounded.

Off a 400-mile stretch of the coast of the eastern United States, more than a score of canyons, or one for an average interval of 15–20 miles, have been mapped. But the wonder of their disclosure grew with the simultaneous discovery of deep and general trenching of the areas separated by the canyons. There the trenches, greatly outnumbering the canyons, differ from them by heading at or below the fall-off at the head of the continental slope. To distinguish these many, somewhat shorter valleys, we shall call them 'slope furrows', or simply 'furrows'. Between each pair of adjacent furrows is a long strip of higher ground; each strip may be called an 'inter-furrow ridge' or simply 'ridge'. Like the furrows and canyons, the ridges run in the general direction of the continental slope, that is, approximately at right angles to the line of fall-off or break of slope of the continental terrace.

The first maps well illustrating the association of canyon, furrow and ridge were made by the United States Coast and Geodetic Survey. From the soundings of 1930–32 the region of Georges Bank was mapped by Lieut. P. A. Smith. Although the soundings were numerous, they were too few to permit unequivocal contouring. Similar failure to portray the submarine relief with complete objectivity and exactness must characterize all other published maps of the kind, especially when depths exceed 1,000 fathoms. Nevertheless, it can scarcely be doubted that in principle all the Coast Survey maps, inside the 1,000-fathom line, give a good picture of the relief.

The next four seasons of exploration covered in large part the continental shelf and slope along the belt from Long Island to a point off Norfolk, Virginia. From the soundings three isobathic maps were drawn by the late A. C. Veatch. This belt, 250 miles long, includes five principal canyons, all heading far back in the continental shelf. To suggest their relative positions, they have been named, in order from north-north-east to south-south-west, the Hudson, Wilmington, Baltimore, Washington and Norfolk Canyons.

---

* From a paper read at the Fiftieth Anniversary Symposium of the University of Chicago on September 25.

The Hudson Canyon is continuous with the Hudson Channel across the shelf. There is no similarly clear relation for any of the other four canyons, though traces of what appear to be true shelf channels appear to east and west of Cape May. It is possible that some of the more southerly canyons are genetically connected with the Delaware and Susquehanna River systems, thus recalling the more direct correlation of the Hudson River, Hudson Channel and Hudson Canyon. On the other hand, it is worth noting at once that none of the canyons of Georges Bank has any obvious or probable relation to rivers of the continent.

The side slopes of submarine canyons are variable but comparatively steep. Along the upper and deeper parts of these valleys, as mapped by Smith and Veatch, the side slopes range from 1 in 3 to 1 in 5 and average about 15° from the horizontal. This is about the angle of rest for soft sediments.

The whole topographic pattern is on a scale nowhere matched on the land, where, however, there are small-scale analogies. Among these are the gullied slopes of many railway cuts. Illustrations are found where the initially smooth sides of the cuttings have exposed weak material, and that so long ago that gushes of rain water have had time to gully the artificial slopes. Particularly fine examples are to be seen along hundreds of miles of railway traversing the southern Appalachians. Another analogy, of more generous dimensions, is the system of rain gullies eroded out of soft Californian formations. At the railway cutting an occasional gully is more deeply incised than the average gully and also heads far back of the break of the slope at the limit of higher ground alongside the cutting. Such an exceptional gully corresponds to the typical submarine canyon.

As yet, soundings in belts other than those around the United States have not been detailed enough to show how general is the furrowing of continental flanks the world over. On the other hand, the more easily discovered canyons are reported off five continents and in the three principal oceans, and it is highly probable that each region with canyons is also intensely furrowed. The distribution of the canyons is world-wide—a fact of great importance for any theory of origin for the great valleys.

From their general similarities we may well assume that at least the majority of the canyons, the world over, were simultaneously developed; and their form seems clearly to imply that they are youthful features of the submarine topography.

Where mapped in detail, the canyons and furrows seem to differ significantly from the Grand Canyon of Arizona and similarly walled, sub-aerial valleys. Although cases of similar variation of side slopes may be ultimately found in the submarine valleys, no systematic alternation of cliff and talus is shown by any of the isobathic maps now published. These last suggest that the layered rocks composing the great continental terraces are, with respect to strength, relatively homogeneous.

A strong indication that in general the sediments offer little resistance to erosion by bottom currents has been supplied by the seismographs of Ewing and Bullard, who have recently reported great thickness for unconsolidated and semi-consolidated phases of the American and European terraces. A similar story is told at the deep borings off the Louisiana-Texas coast. All these determinations are obviously favourable to the preferred glacial-control theory of canyon and furrow.

Another significant set of facts: with a dredge Dr. H. C. Stetson found the canyon walls to include two horizons of sedimentary rock containing Foraminifera. Dr. Cushman refers one horizon to the Miocene and regards the other as probably Pliocene. Thus we have an upper, probably Pliocene limit, for the age of the canyon-cutting. Stetson has also shown that the canyon floor is now being raised by the deposition of fine mud, already a few inches or feet in thickness; and that this muddy layer is underlain by other sediment containing the shells of cold-water marine animals of types expected in these latitudes during a glacial stage of the Pleistocene. The stratigraphy suggests that the valleys concerned were excavated in pre-Wisconsin time, though not necessarily in pre-Glacial time.

Submarine Erosion

Opinion has come to favour submarine erosion as the cause of canyon and furrow. On this basis three contrasted hypotheses have been proposed. Respectively they emphasize principles symbolized by the phrases 'spring-sapping', 'earthquake wave', and 'silty underflow'.

Prof. D. W. Johnson has elaborated the spring-sapping hypothesis. Analogy with the headward growth of valleys in the high plateaux of the south-western United States is emphasized. The plateaux are underlain by alternating beds of porous and tight, permeable and impermeable, rock. The rain water fallen on the high parts of one of these land plateaux sinks to one of the continuous permeable beds, along which the water creeps, down to a lower level where the bed, or aquifer, crops out. Here the subterranean stream issues with some kinetic energy and also with power to dissolve rock matter. Here the relatively weak, porous rock is eroded away, whereby the overlying stronger beds of rock are undermined. Ultimately the undermined rock is torn apart by gravity, with sliding of great blocks into the new part of the gulch. The debris of the slides is further broken up by frost and other weathering agents, and, both in solution and by mechanical washing, is carried away. Thus the new valley is gradually lengthened by 'spring sapping'.

Johnson suggests that the submarine valleys have been lengthened in a similar way. His speculation is based on a number of assumptions: (*a*) each continental terrace includes an adequate number of continuous aquifers; (*b*) these aquifers crop out on the continental slope at the appropriate levels; (*c*) the flow of the ground-water along the aquifers has sufficed to produce trenches of great length and great depth below their respective rims; and (*d*) the removal of slumped rock-debris at each valley-head has been due to solution in the aquifer water. All four assumptions may well be doubted.

While here and there permeable beds have been demonstrated in the continental terraces, we have no evidence that they are abundant enough or continuous enough to match the number of submarine valleys already discovered. Then, too, it is highly improbable that there can be aquifers outcropping near the fall-off to the continental slope, in number sufficient to explain the heading of so many furrows at the line of fall-off. Thirdly, it is clear that most of the canyons are found in regions where both topography and geological structure forbid belief that the fresh water in any aquifer can have a hydraulic head which is adequate to overcome the back pressure of the denser sea water. Examples are seen in the canyoned belts off Georges Bank, off India, off California, and off the west coast of Africa. In my opinion, the same is true in the case of the belt off the eastern United States. In the fourth place, it is a question whether the issuing aquifer water would not be largely saturated with rock matter dissolved from the porous bed itself and to that extent incapable of dissolving rock debris in the hypothetical new gulch. If the issuing water is not saturated, it is likely to be less dense than the sea water, in which it must rise and thus lose contact with the rock debris entirely. Evidently solution of the slumped debris would be out of the question. A final and likewise telling objection: the spring-sapping hypothesis postulates important solution of one of the least soluble materials known to geology—clay. With that premise neither geologist nor geochemist is easily satisfied.

The second hypothesis which is based on the postulate of a submarine origin is that of Prof. W. H. Bucher, who attributes canyon and furrow primarily to cutting by reflux currents associated with powerful earthquake waves in the ocean. But here, too, there are troubles. That part of the energy which belongs to the reflux current is largely concentrated near the surface of the ocean, the velocity of the motion decreasing with great rapidity as the depth of water increases. The laws of hydraulics demand that even the mightiest seismic wave cannot give a reflux current fast enough to erode the lower half of the continental slope, down which, nevertheless, the submarine valleys continue for many miles. Further, the earthquake waves run in packs, as so-called trains of waves, but no train of waves attacks a coast for more than an hour or so, and none attacks it more than once in a stretch of time measurable in decades or centuries. In fact, no major earthquake wave has ever been recorded in the North Atlantic, where submarine valleys are in full development. The possibility that in prehistoric time this ocean was long shocked much more vigorously than at present is emphasized by Bucher, but only in a purely speculative way and without proof. Similarly there is no evidence that such reflux currents have been powerful and numerous enough to account for the valleys sunk in the continental terraces of the Indian Ocean or the eastern Pacific, from Vancouver to southern California.

Influence of Glacial Control

The third explanation based on the assumption of submarine erosion adopts the idea of glacial control and, in my opinion, is by long odds the most satisfying of all the published attempts to account for these submarine valleys.

About 40,000 years ago, the last set of Pleistocene ice-caps of North America and Europe were of maximum total volume, but were just beginning to melt away. With the exception of a few small patches, the last remnants of the gigantic masses of ice had disappeared by the year 7000 B.C. Since the water of the ice-caps had been evaporated from the ocean and then dropped, as snow and rime, on the lands, the sea-level was lowered all around the globe. The lowering was about 300 ft. in maximum.

From the amount of work done by the last set of ice-caps, it appears that sea-level was nearly as low during a period of the order of 50,000 years. During three long intervals of still earlier Pleistocene time, ice-caps had slowly grown to comparable size and then melted away more or less completely. The second glaciation seems to have been more extensive than the last one, and may be thought to have lowered sea-level a little more than 300 ft. During tens of millennia each set had maximum total volume; and during still other tens of millennia each set was slowly melting. From beginning to end of each of the four glacial stages—chaptered as growth, culmination and waning—the wind waves and tidal waves were breaking on the continental shelves, far out from the existing shore lines. Thus, for a time totalling more than a quarter of a million years, the waves were pounding the old embankments of clay, mud and sand. Along the temporary, slowly migrating shores, storm wave and turbulent tide were muddied to a degree far beyond that represented in the 'longshore water of the present day. While so charged with particles of solid rock, the silty water was effectively denser than clean sea water, and as a temporary suspension, sank bodily to the bottom, that is, to the surface of the continental terrace. There the specially weighted water flowed slowly down the gently sloping continental shelf, to run much faster after it had passed the fall-off at the top of the continental slope. Such accelerated density currents along the sea floor were, according to the hypothesis now to be discussed, the chief excavators of our submarine valleys.

The compulsion on silt-laden water to dive and slide along the sea bottom was, of course, lessened in proportion to any settling-out of solid particles. However, such loss of excess density took time. Observation shows that shore waters, agitated by a storm, remain murky with sediment for many hours after the storm has spent its fury. We may therefore assume that a bottom current of Pleistocene time could run many hours. Over the gently sloping shelf its velocity was comparatively small, and over this region some of the coarser detritus must have settled out. But, according to the hypothesis, the zone of agitating waves was long situated at, or close to, the fall-off to the continental slope. Without delay the silty water would be precipitated down the continental slope, and that with a velocity much greater than any possible on the adjacent shelf. With only moderate velocity the silty current would cross the whole slope in some hours. If, during those hours, the speed were enough to cause turbulent erosion of the slope sediment, the settling-out would be delayed and new solid particles added to the soup-like suspension. Nowadays the zone of intense agitation by the breakers is 50–150 miles from the outer edge of the flat shelf; hence now, during the long, slow journey to the fall-off, a bottom current loses much of its operating load by settling out and therefore cannot attain great speed down the continental slope. Is it not clear that the silty currents of each Glacial stage should have been incomparably more energetic on the slope than any current developed by storms in post-Glacial time?

Quantitative Tests

Quantitative testing of this glacial-control hypothesis presents some difficulty. Essential facts are buried in both space and time—under the ocean and under the obscuring blanket of post-glacial and glacial time. Yet there are already in sight valuable tests, which, taken together, greatly encourage faith in the root idea as the most promising of all those reported in print. These tests are based on illuminating analogies in Nature, on laboratory experiments, and on an engineer's formula relating to the flow of liquids under gravity.

An obvious analogy is that of the ordinary river, which also flows along the bottom of an ocean—an ocean of air. One condition for its descent is its possession of density greater than the density of the covering air. Similarly, the silty submarine current runs down the continental slope because the density of the mud-charged water is greater than the density of the covering clean water.

More than half a century ago Forel studied the behaviour of the Rhone where its water, made milky with suspended rock-flour that was brought from the high glaciers of the Alps, enters Lake Geneva. Any summer visitor on the heights above Montreux can see the whitish, silt-laden water of the river deployed on the lake for some distance. He can see that this water is sharply bounded against the blue water of the lake. With simple apparatus Forel proved the sharpness of contact to be due to an almost vertical plunge of the silty water to the bottom of the lake. He thus showed that the silty current does preserve its individuality under the lake water. But to what distance ? Forel found the answer to this query also. He noted that the sub-lacustrine delta of the Rhone is interrupted by a channel-like furrow, extending six miles down the delta, measured from the point where the silty water makes its initial plunge. This point is just outside the jetties at the mouth of the Rhone. The depth of the channel below its rim is considerable, with maximum of nearly 200 ft. Forel imagined two possibilities: first, that the channel has been dug by the bottom current; second, that the channel is the result of preferential deposition of the silt where the bottom current loses velocity by friction against the stagnant lake water on either side of the current. The latter process would be analogous to the levee-building along the lower Mississippi River. Forel ultimately found more satisfaction with the second explanation of the channel. On the other hand, a much later study led Dr. Romieux of the University of Geneva to favour the erosion hypothesis. But, whether erosion or differential silting of the lake floor, or a combination of the two processes, be the true mode of origin, it is clear that the Swiss limnologists believe in the persistence of the bottom current to a distance of six miles. Their conclusion deserves strong emphasis in the discussion of submarine valleys.

Switzerland has a parallel case. The contoured map of the Rhine delta under the surface of Lake Constance portrays a trench across the delta with dimensions much like those of the Lake Geneva channel. Be it noted, too, that each of the Swiss channels has a slope which is less than one two-hundredth of the average slope down the flank of a continent.

For our problem, analogy becomes still more illuminating when we watch the course of a muddy river that enters a long reservoir, created by an artificial dam at the opposite end. An ideal case is represented where the Colorado River penetrates Mead Lake, a reservoir with a length of about 120 miles, measured from the celebrated Boulder Dam that holds up the water level. Since progressive silting and shallowing of the reservoir are inevitable, Government engineers are systematically measuring the proportion of solid matter suspended in the water at the intake, and as systematically tracing the course of this weighted water after entry into the reservoir. Cloud-bursts upstream from the lake suddenly increase the volume, velocity and silt-content of the torrential river. At the intake, the point where the muddy Colorado enters the reservoir, the time of arrival of water with maximum muddiness is noted. Some days thereafter the same water, still charged with an extra load of suspended silt, appears at the penstocks of the dam, now 120 miles below the intake. That the muddy current hugs the sloping bottom of the lake has been proved by sampling the water from surface to bottom and at various vertical sections between intake and dam.

Above each muddy sheet the reservoir water, hundreds of feet thick, was almost entirely free from suspended particles of rock. Here, then, we have another proof that a silty current does not lose its individuality by mixing with the overlying clear water or by the settling-out of the silt. In the case of Lake Mead the bottom current persists for as much as 150 hours, one of the measured times for the traverse of 100 miles in the lake.

By identifying individual influxes of muddy water, engineers have been able to measure the average velocity of the current between intake and dam. In one instance the rate was found to be about half a mile per hour—a notable speed for a current following the average gradient of the floor of the reservoir, namely, a gradient of only 7 in 10,000 or less than 1 in 1,000.

The Elephant Butte Reservoir, in the Rio Grande valley, receives the inflow of the Puerco River, which in flood is charged with fine sand and mud to an extraordinary degree. Here too the muddy water is seen to dive along a sharp line of demarcation at the surface and then follow the gently sloping bottom of the reservoir to the retaining dam, the surface water remaining "perfectly clear". The sub-lacustrine journey is about 35 miles in length. Although the measured thickness of the silty current is comparatively small—only five feet in one reported case—and, although the bottom gradient averages only 1 to 1,000, the velocity of the bottom current has registered as much as 1·5 miles per hour. The high speed is explained by the unusual muddiness of the Puerco River at time of flood. After the entry of its water into the reservoir, a cubic foot of this water weighs two to three pounds more than a cubic foot of clear water at the same temperature.

Bottom currents, similarly motivated by suspended silt, have been demonstrated in four other American reservoirs—Lake Lee (North Carolina), Lake Murray and Saluda Reservoir (South Carolina) and San Carlos Reservoir (Arizona). The Government engineers have thus good ground for the conclusion that underflow of the kind described is a "general phenomenon in reservoirs" subject to inflow of muddy water on the grand scale. The silty water slides down the floor of a reservoir "much as water itself flows under air".

Small-Scale Tests

The studies at Lake Geneva, Lake Constance and the six artificial lakes in the United States have established two fundamental facts: first, a silty underflow persists, with much of its initial velocity, for many hours and even as much as seven days; second, the speed of flow can exceed one mile an hour although the slope traversed is only 1 to 1,000, and although the thickness of the bottom current is only a few feet. Since the continental slope is about 1 in 15, and since the thickness of the silty current of glacial times must have been at least 100 ft. and probably more, we already have, from analogies in Nature, some good quantitative support for the preferred explanation of the submarine canyons and furrows. But other quantitative criteria as to the worth of the explanation should be found if properly controlled experiments are made in the laboratory. Knowing that experiment is the principal tool of science, Dr. P. H. Kuenen, of Holland, has called on the resources of the laboratory. He had three objectives: to devise a visual test of the possibility that silty currents can long preserve their individuality, even though the motivating silt tends to settle out; second, to measure the velocities under controlled conditions regarding current density and slope of channel; and, third, to determine whether a current, flowing fast, will add to the suspended load and therefore run still faster. Kuenen succeeded with all three problems, and not the least significant of his conclusions is that a strong bottom current running down a continental slope may readily become self-accelerating and thus endowed with new self-generated power to erode. Some of his experiments will be briefly described.

In a glass-walled tank, 15 ft. long and 2 ft. deep, a model of a 'continental terrace' was built of sand surfaced with hard gypsum. The 'shelf' had a gentle slope as far as the fall-off of the 'continental slope', which had a gradient of about 1 in 7, or one typical of the upper part of the average continental slope in Nature. Water was poured into the tank until it topped the 'shelf' by a few millimetres or centimetres. Just above the fall-off a strip of wood with a rubber flange at the bottom was placed across the tank. Behind this bar, water with various proportions of solid particles in suspension was gently poured on the 'shelf'. The bar was then removed. The silty water at once began to flow down the 'continental slope' in the form of a lively current.

It was found that any slight crease or depression directed down the 'continental slope' tended to draw the silty water from right and left, thickening the current and correspondingly increasing its velocity. A tongue of the silty water ran down ahead of the more slowly flowing suspension on each side of the tongue.

Similar suspensions were released after the hard surface of the model was covered with thin layers of clay. When only moderately charged with 'silt', the density current became turbulent soon after passing the fall-off. With the onset of turbulence the current began to deepen the initial depression directed down the 'continental slope', making this into a 'canyon' or 'furrow'. With the erosion went a gain in load for the current and also measurable acceleration of its velocity. Thus Kuenen proved once more that "to him that hath shall be given".

In order to make more vivid the evidence for erosion and self-acceleration of current, both to the eye and the camera, clear solutions of salt in water were released on the 'shelf', this time covered with a thin layer of white mud.

Kuenen measured the velocities of flow and was able to estimate the average thicknesses of the moving sheets of 'heavy' water, as seen through the glass walls of the tank. Knowing also the slope of the bottom, he had the data for applying an engineer's formula, which, with proper precautions, can be used to calculate the velocity expected for a current flowing steadily down a continental slope. This formula is $v = c\sqrt{m.s.d}$, where c is a constant, v represents the velocity, m is the so-called hydraulic mean depth (the cross-section of the current divided by its wetted perimeter), s the slope, and d the effective density of the flowing material.

From the measured values of v, m, s, and d in the case of a bottom current at Lake Mead, Dr. Kuenen deduced an approximate value for c that would match the conditions for erosive furrowing of the continental slope. In the centimetre-gram-second system of units, the value for c came out at 400. For our problem let us assume m to be 5,000 cm.; s to be 1/15; and d to be only 0·0005. With corresponding substitutions in the formula, the velocity is found to be about 160 cm. per second or 5·75 km per hour or 4 miles per hour—a velocity sufficient to move coarse gravel and to tear up silt and sand. Silty currents set running by major storms in glacial times must have had initial effective densities higher than 0·0005; nowadays wave-stirred, silty waters have measured densities twice as great.

Dr. Kuenen's experiments are particularly eloquent in showing that, if the current, running down the muddy continental slope, reaches a velocity of only two miles an hour, it should take up a new, additional supply of mud and should, therefore, run all the faster and erode still more efficiently. This new power would, of course, be lost again when the current reached the lower, flatter part of the continental slope. Kuenen's own graphic statement may be quoted: "The part played by the shelf is now thought to be that of the ringing voice loosening an avalanche. If the density of a comparatively small volume of water is once raised above that of the deeper strata, the flow is set off. It gathers volume and speed on the way down and takes up more and more silt. Given a little help the canyon erodes itself." This conclusion is all the more acceptable when it is remembered that the terrace sediments are water-soaked, hence highly mobile, and deposited near the angle of rest. Such material at the angle of rest will yield readily if its back is even gently brushed by a downhill current.

Conclusion

Looking back, we see that the preferred, glacial-control explanation of canyons and furrows covers the essential facts, which may be listed as follows: (1) the comparative youth of the topography; (2) its world-wide, planetary distribution; (3) the similarity of the continental slopes to the gullied hill-sides on land; (4) the evidence that canyons are now being slowly filled with mud; and (5) the discovery of cold-water shells (foraminifera) in the clay that underlies the new muddy layer of incipient filling. Incidentally, the study of silty currents has indicated a mechanism for the transport of shore sediment to water depths of 2,000 fathoms and as far as 100–200 miles from the land where the sediment had been manufactured. This long travel of sand and mud has long been a puzzle. The silty-current hypothesis is favoured by the weakness of the terrace material, by the steepness of the continental slope, by the visible proof that shore waters are muddied through agitation by storms and tides, by laboratory tests, by the teaching of Nature in the Swiss lakes and in artificial reservoirs, and by the failure of all other hypotheses yet offered to account for the submarine valleys.

THE TEACHING OF SCIENCE

AT the Conference on Science and the War Effort arranged in London recently by the Association of Scientific Workers, there were two sessions devoted to the university training of scientific workers and the training of technical personnel. These sessions, which were attended by well over a hundred people, were remarkable for the wide range of teaching activity represented among both speakers and audience. Nearly every sphere of science teaching was represented, and the speeches dealt with ordinary university and polytechnic courses, the training of State bursars, the part-time teaching of young people in factories and workshops and the special training of recruits and cadets for the Forces. The limitation of time made it impossible to discuss at any length the teaching of science in secondary schools, but it was realized that the problem of scientific education must be tackled as a whole and that the school part of this is of fundamental importance.

Many of the questions discussed were not new, but the present war situation has brought all the old questions sharply to the fore along with some new problems. At the opening of the session on technical education, Mr. E. G. Savage, education officer to the L.C.C., who presided, said that the importance of technical education and the training of technical personnel needs no emphasis at this moment. As we are already bitterly aware, we are engaged in a war in which the quantity and quality of technical personnel is of the highest possible importance. Had we been better prepared in this matter at the outset of the War, it is possible that in at least one field of operations there might have been a different story to tell. As it is, we have been busily engaged in making up very substantial leeway. It is, however, equally important and very relevant to point out that the necessity for trained technical personnel will not diminish when peace comes. Mr. J. M. Keynes was recently quoted as saying that there is no necessity for us to be poorer for very long after the War. Given a proper use of the material resources of the earth and of the skill of our people, we should look forward to an even higher standard of living after the War than before it. To realize this happy issue, however, it is obvious that we shall need much more widespread and much more efficiently trained scientific and technical personnel in our industries and elsewhere.

Mr. J. A. Lauwerys, of the Institute of Education, University of London, said that we lack technically trained people because our secondary education, based on the study of language and literature, is out of touch with the requirements of an industrial society. The traditions which we inherited from ancient slave societies still dominate many of those in charge of our education. They still believe that the studies of highest educative value are those which have nothing to do with the production of useful commodities, and we are suffering from the widespread acceptance of the wrong view that 'culture' and 'vocation' should be kept separate. The question of elementary technical education involves several problems, but the core of the education we need must be scientific studies and not purely literary ones. That is not to say that we should support the proposals of the reactionary and outdated Spens Report with its deplorable suggestions that there should be grammar schools for future administrators, business men, etc., and technical high-schools for future skilled workers. To accept this would be to deepen the existing cleavage, the evil results of which have been and still are plain to everybody.

Dr. E. A. Rudge, of the West Ham Municipal College, said that the present difficulties in the supply of scientifically and technically trained people can only be met by the reorganization of schemes of education. This branch of teaching has been neglected over the past twenty years, and the salvaging of technical education should be regarded as a major part of the war effort. The necessary reorganization should be on a national basis, and the scope of local government control should be strictly limited. The raising of the school leaving age is necessary, and this would involve the abolition of fees for full-time students proceeding to technical vocational training. The scientific and teaching professions should recognize the inadequacy of present makeshift methods of selection and training, and must plan long-term and carefully organized schemes of education. He urged that we should strive for the setting up of a national advisory committee, including representatives of the scientific and teaching professions, of industry and of the Board of Education.

The important question of part-time training was discussed, and it was generally felt that the scope of this should be much extended. But this part-time education must be closely linked to the actual work being done in the factory or workshop, because most young people learn better when they feel that the subject is important and see its relevance. Although the better employers have for a long time allowed boys to attend part-time courses during working hours, this practice is by no means universal. The Essential Works Order requires firms to provide facilities for technical training, and if this were interpreted to include attendance at technical classes, inside or outside the factory, during working hours, there would be a considerable gain in technical efficiency. It would be desirable to start a sort of tutorial system whereby specially selected men co-operate with the educational authorities in the training of young people.

In this connexion the very important question of vocational guidance was raised. It was felt to be very desirable that there should be a great extension and systematic use of vocational guidance aimed at leading pupils fitted by capacity and inclination into well-designed courses of industrial training. The provision of such guidance on a large scale is a big problem, and it involves other problems such as how to make employers rely on the scheme and how to make it easier for young people who are misfits to change their jobs.

In the discussion on part-time training an important point in connexion with university and hospital laboratories was raised by Mr. B. E. Gilbey. The technical workers in pathological and bacteriological laboratories have developed, largely by their own efforts, into highly trained technologists. Their training extends over five years and is extremely haphazard, depending largely on the good-will of the senior members of the staff, so that they have to have recourse to evening classes which are often unsuitable. The unorganized training and the lack of professional recognition is resulting in the loss to an important profession of a large number of potential technologists at a time when they are urgently needed.

The inadequacy of the scheme of scientific education in the schools of Great Britain has been strongly underlined by the difficulties facing those who have to train technical personnel in the Services, and these difficulties were discussed at the sessions. There is a shortage of scientific knowledge throughout every grade: there are too few people with degrees, too few with higher school certificate science, too few with matriculation science and too many with no scientific background at all. Scientific weapons and devices have been perfected far more rapidly than people have been trained to use them, and so the limit of efficiency and success is in many cases set by personnel and not by technical advance. Although much has been done recently in many secondary schools, most private schools give little education in science, and the percentage of girls in the Auxiliary Forces with scientific knowledge is very small.

The present situation has vindicated completely those who have fought for the lengthening of the school period and for more science teaching. The need to-day is not only for a wider knowledge of the laws of physics and chemistry, but also for a more scientific attitude to all problems. To take only a few instances, there is a need for the Forces to have more understanding of the usefulness of controlled experiments, of statistical analysis of results, and of scientific tests for the selection of personnel. In some directions the work is good, and this is particularly so where civilian scientific sections responsible for the initial inventions have been asked to help in training. Members of these have the special task of following the new apparatus into operational use, and they have both advised on and taken an active part in the instruction of suitable personnel. In many cases, however, the training covers too narrow a field and is carried out without any regard for educational principles. There are many cases of people being taught to perform some process without being given any idea of where it fits in or even of why they are doing it.

It is quite clear that there is a great need for more technical officers in the Forces who have some training in educational methods, and for people with such training to join the civilian sections. On the other hand, it is vitally necessary that the military authorities should make the fullest use of those members of the Forces who have been trained in technical subjects or in educational methods. In the selection of personnel some sections make good use of psychological tests, but in others deportment, type of school, accent and pure chance still play a large part. This is to be deplored, though in this sphere, as in so many others, the continued efforts of those who are alive to the situation have produced good effects; but much remains to be done.

The session on the university training of scientific workers was presided over by Dr. W. A. Wooster, of the University of Cambridge, and the opening address was by Prof. J. A. Carroll, of the University of Aberdeen. Prof. Carroll stressed the need in modern civilization for a much wider scientific education in addition to the training of the specialist. University science teaching must abandon its present relative isolation and relate itself to its sources, the schools, and to its ends, the production of future teachers, of research workers and of people with a general education. The majority of students do not become research workers, so for the majority the courses are too detailed and too long. We need three types of university science courses: general honours courses for those who are going to teach in schools; special research and technical courses; and general cultural courses for those who intend neither to teach nor to do research.

As regards the supply of young people for university science courses, it is clear that the conditions of entry into British universities require modification. The development of junior, secondary and technical schools might prove very dangerous, because it might easily happen that pupils from these would be cut off from universities under the present conditions of entry. Prof. Carroll stressed the point that the reform of the educational system of Great Britain is long overdue, and that we are paying dearly to-day for the lack of common appreciation of the part which science could play in improving the conditions of life of the community. He also urged the setting up of an advisory committee on scientific education to advise the Board of Education.

The special effects of the war on the problems facing university science teachers were dealt with Mr. R. T. Lattey, acting director of the Electrical Laboratory, Oxford. He spoke of the present teaching of physics there, where four types of students have to be considered—more or less normal undergraduates, State radio bursars, Royal Corps of Signals cadets, and R.A.F. cadets. The most difficult part of the work is to instil a scientific outlook into immature minds, as most of the students have the idea that learning by rote is the end of all knowledge. The bursars come from all types of schools and the qualifications for bursarship as drafted are well below scholarship standard. The scheme can, therefore, be looked on as an interesting experiment of sending to a university pupils who would not get a scholarship in normal times. These students have turned out to be better than might have been expected, and it is clear that the average student has a considerable latent scientific interest and capacity.

Dr. V. E. Cosslett, of the University of Oxford, urged that as an immediate measure there should be proper organization and allocation of available laboratories and the depleted numbers of teaching staff. Very little has been done in the grouping of teachers and courses. Such steps are urgently demanded, for example, in the case of evacuated colleges, and it is certainly true to say that the best possible use is not being made of the limited number of teachers remaining in the universities and colleges.

The sessions on scientific and technical education were very successful in opening up the whole question, and in providing a broad view of the numerous problems involved. Among the speakers and those who took part in the discussion there was unanimous agreement on all the principal issues. The Association of Scientific Workers has begun to form a committee charged with the task of co-ordinating the experience and efforts of all those who are attempting to increase the quantity and improve the quality of scientifically and technically trained people in Great Britain. This is an effort which must succeed if we are to win the War with a minimum of loss, and if we are not to fall hopelessly behind certain other nations in the period of rebuilding after it.

We welcome the decision of the Association to form this committee and hope that it will develop a broad and comprehensive point of view, thus dealing effectively with science teaching in *all* educational institutions, for faulty education can obviously pass from teacher to taught, or from university to school, and vice versa.

OBITUARIES

The Earl of Berkeley, F.R.S.

RANDALL THOMAS MOWBRAY BERKELEY, eighth Earl, was born on January 31, 1865, and died on January 15. He was head of the historic house which acquired the Berkeley lands in the twelfth century, and is among the very few that can rightly claim a pre-Conquest pedigree ; even the critical genealogist Horace Round allows the Berkeley descent from Eadnoth the Staller, an officer of the household of Edward the Confessor.

In feudal days the Castle of Berkeley was held directly of the King, so that its owner was a baron by tenure, a status which in 1421 was merged in a summons by writ and a hereditary peerage. Since such baronies can be held and transmitted by females, on the death of the sixth Earl in 1882 it passed to his niece, wife of General Milman, who thus became Baroness Berkeley, while the earldom, created in 1679, went to a cousin as heir-male. For some seventy years this title had not been assumed, while there was doubt about its inheritance, leading to a famous lawsuit. Meanwhile the lands were in possession of the Lords Fitz-Hardinge. But in 1891 Randall Berkeley established his claim to the earldom before the Committee of Privileges.

Lord Berkeley began his active career in the Royal Navy and reached the rank of lieutenant. But being drawn to scientific research, he left the Service and built a laboratory at Foxcombe, on Boar's Hill near Oxford, a house which he much enlarged, adding a really fine stone hall. It is now the Theological College known as Ripon Hall. There he carried out his experiments, the success of which was shown by his election to the Royal Society in 1908.

Berkeley's work centred around the idea of measuring the physical properties of concentrated solutions, in order to test the possibility of applying to them equations of the type of that used by van der Waals for gases, vapours and liquids. The fundamental determination required is obviously that of osmotic pressure, either measured directly, or deduced by the principles of thermodynamics from the measured vapour pressures. To obtain accuracy in the results, many and great experimental difficulties had to be overcome. The original method of directly measuring osmotic pressure, invented by Pfeffer, is quite unsuitable when concentrated solutions are used. Instead of allowing solvent to enter a porous porcelain cell closed by a semipermeable membrane of copper ferrocyanide until equilibrium is obtained, Berkeley and his colleague E. G. J. Hartley deposited the membrane in the walls of a porous tube with its ends sealed, and varied the hydrostatic pressure on the solution until no further movement, either in or out, occurred. From 1904 until 1919 a series of papers, most of them in the *Proceedings* or *Transactions of the Royal Society*, appeared from the Foxcombe laboratory, gradually improving the methods and results, and dealing with other allied subjects, such as the vapour pressures and densities of solutions of varying temperature and concentration. The results of the measurements on bodies like sugars were shown to conform with equations such as

$$\left(\frac{A}{v} - p + \frac{a}{v^2}\right)(v - b) = RT.$$

Berkeley had an instinctive grasp of the methods of science and, moreover, had the skill, thoroughness and patience to apply them to his complex problems.

In 1916, on the death of his kinsman, the last Lord Fitz-Hardinge, Lord Berkeley inherited Berkeley Castle and the Berkeley estates, comprising valuable property in London as well as the lands in Gloucestershire. He left Boar's Hill and devoted himself to the restoration of Berkeley Castle and to other local activities ; for some time he was master of the Berkeley Hounds. His first wife was the widow of Mr. Arthur Jackson. She died in 1898, after which his step-daughter, Miss Sybil Jackson, acted as hostess at Foxcombe. In 1924 he married as a second wife a daughter of John Lowell, of Boston, U.S.A., with whom in these later years he spent much time in Rome and California. He had no children by either marriage and the romantic Earldom of Berkeley becomes extinct. W. C. D. DAMPIER.

Dr. F. Holweck

IT is reported that the French physicist Fernand Holweck died recently in Paris, but the circumstances of his death are not clear.

Fernand Holweck was both a scientific worker and a technician. He had been educated at the École de Physique et de Chimie Industrielles de la Ville de Paris, where Pierre Curie had taught, and became, first an assistant, then a "Chef de Travaux" in Madame Curie's laboratory. He had received the title of Maître de Conférences.

His first important work, for which he received the degree of doctor of science, was on the X-rays of long wave-length (1920–25). He actually filled the gap between the soft X-rays and the extreme ultra-violet rays, by studying the absorption discontinuities characteristic of the K- and L-levels of light elements. Later (1928–38) he extended the study of soft X-rays to their action, and specially their quantic action, on bacteria and viruses.

In the technical field, so early as 1923, Holweck made a helicoidal molecular pump, and a radio emitting valve which could be opened for the replacement of the electrodes. Both proved to be very useful improvements at the time, and were adopted by the French Navy. Later, in collaboration with R. P. Lejay and P. Chevallier, Holweck constructed an improved portable pendulum for gravitation measurements, and he had been working on this subject since 1930.

F. Holweck received in 1927 the Pierson-Perrin Prize for his work on soft X-rays. In 1936 the Paris Academy of Sciences awarded him the Prince Albert I of Monaco Prize for his work on gravitation.

In the War of 1914–18, Holweck served as radio operator. He was married, and had three children. He was a friendly man and liked to crack a good joke. His inventive spirit, his creative skill and his good nature will be greatly missed by physicists.

A FREE FRENCH SCIENTIST.

WE regret to announce the following deaths :

Dr. W. P. Durfee, emeritus professor of mathematics and emeritus dean of Hobart College, Geneva, N.Y., on December 17, at the age of eighty-six.

Dr. Cornelis Winkler, formerly professor of neuropsychiatry at Amsterdam, and honorary member of the Sections of Neurology and Psychiatry of the Royal Society of Medicine, aged eighty-six.

NEWS and VIEWS

Prof. R. A. Daly: Wollaston Medallist

The Wollaston Medal of the Geological Society of London is awarded to honour those who have made "researches concerning the mineral structure of the earth". The very appropriate choice of Prof. R. A. Daly to be this year's recipient of the Medal will be endorsed with enthusiasm by his many friends and admirers. A Canadian by birth and a graduate of the University of Toronto, Daly began his long association with Harvard in 1892, first as a graduate student and afterwards as an instructor in geology. In 1901 he resigned this post to take up a Canadian appointment as geologist on the International Boundary Commission. Ten years of work resulted in a map of, and report on, a 400-mile belt along the 49th parallel from the Pacific, across the Western Cordillera, to the Great Plains. The two following seasons were devoted to the C.P.R. section through the mountains. These arduous years gave him the experience that led to the writing in 1913 of his most famous book, "Igneous Rocks and their Origin", which, rewritten twenty years later as "Igneous Rocks and the Depths of the Earth", remains as an outstanding contribution to petrology. On the resignation of W. M. Davis from the Sturgis Hopper research professorship at Harvard in 1912, Daly was selected as his successor.

This attractive appointment, which enables its incumbent to teach as little and to study and travel as much as he pleases, gave Daly the freedom to carry out a large number of fruitful investigations, many of them based on field studies in distant lands, including South Africa, many of the classic areas of Europe, and a number of oceanic islands. Among his results, presented in a most stimulating series of papers and books, are new theories of granite formation and emplacement, of the origin of alkali rocks, of the mechanisms of volcanic action and mountain building, of the origin of coral reefs and, most recently, of the origin of submarine valleys (see p. 156). Daly has an enviable flair for correlating and attempting to explain the facts of observation—indeed, it is now an old Harvard tradition that "Every morning in the year, Daly has a new idea !"—and it is therefore not surprising that in recent years he has made himself a master of the modern geophysical methods of attacking the fundamental problems of the earth's structure and thermodynamic history. He has, moreover, done much to initiate and guide the long stream of co-operative geophysical research which Harvard has sponsored. Eloquent and influential teacher and writer, and a prolific and successful worker in a variety of challenging fields, he has deserved well of his fellow-geologists and has abundantly earned the honour now conferred upon him by the Geological Society.

Parliamentary and Science Committee

The significance of the contribution being made by science to the war effort was the keynote of the addresses delivered at the first annual luncheon arranged by the Parliamentary and Science Committee (president, the Earl of Dudley), and held on February 3. This body, it will be recalled, was constituted in 1939 to take over the functions of the Parliamentary Science Committee. It consists of members of both Houses of Parliament, and some twenty-seven organizations concerned with scientific activity are affiliated to it. Its purpose is to provide a permanent liaison between scientific bodies and Parliament.

Lord Hankey, Minister without Portfolio, reminded his audience that from his work with the Scientific Advisory Committee, the Engineering Advisory Committee and the Technical Personnel Committee, he is in constant touch with scientific and technical men, and he paid a warm tribute to the eagerness with which they have responded to the call for their services. He then described in general terms some of the steps which have been taken to utilize scientific effort.

The Scientific and Engineering Advisory Committees work in close association, and often through the medium of *ad hoc* conferences formed from appropriate members of the two Committees and with the aid of independent scientific workers. Co-operation with the United States and with the Dominions has been arranged, and there is a constant exchange of individual men of science and of scientific information. So far as Great Britain itself is concerned, Lord Hankey said that all three Fighting Services are "science-conscious"; scientific men are being used, even in the operational side, both individually and in teams, while the universities and technical colleges are providing intensive scientific training for the great numbers of men and women required to operate scientific war apparatus. The reliance on science during the War is, in Lord Hankey's opinion, going to have a big influence on statesmen and officials in the days to come, and he concluded: "I hope and believe that the association of science with government in our hour of need to-day will continue after the War."

Sir Henry Tizard, rector of the Imperial College of Science and Technology, who is now working with the Department of Research and Development, Ministry of Aircraft Production, began by referring to the sense of frustration under which many experienced scientific men are suffering; the present Government and Parliament, however, attach more value to the help and guidance of scientific workers than have any previous Parliament. Science, like war, he pointed out, has its strategy and its tactics. The tactical strength of science in Great Britain is very great; there are well-equipped experimental establishments and, thanks to the innate abilities of our race and to progressive educational policy, a large number of young workers giving high service to the State. The strategical position of science, however, is not so good. In pure science, the fundamental strategy is to attack at the weakest point of the barrier to knowledge; in applied science, the attack must be made where the best results are obtainable. The choice of problem is of crucial importance, and for decisive results effort must be concentrated on it to the exclusion of other matters. The strategy of science in the war effort can only be determined by ever closer collaboration of the man of science with the executive staffs of the fighting and other services. Sir Henry concluded with a striking comparison. The two great driving forces of Western civilization are science and Christianity. The principles and ideals of science, no less than those of Christianity, must sustain and guide all political action which fights for liberty and social progress.

New R.A.F. Bomber

TECHNICAL particulars of the Short 'Stirling', the heaviest bomber of the R.A.F.'s equipment at present in production, have just been released. Squadrons of these machines have been in regular use for long-distance raids for more than a year. Its general dimensions are: length 87 ft., wing span 99 ft., height 23 ft., approximately, and its total all-up weight thirty tons. It carries a disposable bomb load of eight tons. It has a maximum speed of 300 m.p.h. with a range of 2,000 miles, a considerable achievement for a machine of this size; but its principal feature is its manœuvrability which, combined with a heavy armament, makes it capable of protecting itself against air attack by enemy defensive fighters. It has eight 'Browning' machine guns, divided between three gun turrets, in the nose, mid-top, and rear of the body. A crew of seven is the normal complement, and the interior of the body is sufficiently roomy for any of these to man the guns in an emergency. Special precautions are taken against fire, which include carrying all the fuel in self-sealing tanks in the wings well away from the body. The attention that has been paid to the design of the controls in order to obtain good manœuvrability has resulted in extra steadiness in flight in bumpy weather. This not only adds to the comfort and efficiency of the crew, but also provides a steady platform for bomb aiming. The bombs are carried in a central bomb bay, more than forty feet in length inside the body, and are released through hinged doors in the floor.

British Association and the Social Sciences

IN considering possible action in relation to a number of suggestions put forward at the recent conference on "Science and World Order", the executive committee of the British Association's Division for the Social and International Relations of Science has adopted the plan of inviting representatives of specialized bodies and interested individuals to confer with it on particular questions. A preliminary report of these proceedings will be made shortly. Meanwhile, in view of the articles in NATURE of January 24 on the social sciences, the executive committee thinks it will be of interest to announce that such a meeting as has been described above is to be held on February 18, to consider whether the Association, through the Division or otherwise, can take any appropriate action in relation to the position of the social sciences and, if this be found desirable, to take measures accordingly.

Preservation of Stored Wheat in Australia

THE chief insects infesting wheat in Australia are the two true weevils, *Calandra granaria* and *C. oryzae*, and the lesser grain borer, *Rhizopertha dominica*. The last-named threatens to be the most serious pest of bulk-stored grain in the immediate future, being favoured by the high temperatures which, for reasons still somewhat obscure, frequently occur in silos. Every effort is being made to prevent a repetition of the plague conditions of the War of 1914–18. Of precautionary measures, the selection of mean low-temperature localities for stack storages is highly important but not always possible, especially in the western wheat areas. Liquid contact insecticides are proving more effective than the mechanical methods used in the past for sterilization of infested premises, dunnage, stacking sites, etc. Treatment of the grain with certain finely ground non-toxic mineral dusts has been very satisfactory from the entomological point of view; but objection is raised to the resulting appearance, while the change in angle of slip of dusted, as compared with clean, poured wheat, introduces quite a big and unexpected practical difficulty in modern bulk-handling procedure. Though stacked wheat cannot be readily fumigated, tests in silo bins have been successful, and in Western Australia fumigation of bulk wheat is likely to be adopted on a large scale. So far the problem presented in Australia is much less severe than it became in 1914–19, and every effort is being made by the Wheat Board, in collaboration with the Council for Scientific and Industrial Research, to ward off serious developments.

Protective Gear on Power Supply Systems

AN interesting paper entitled "The Management of Protective Gear on Power Supply Systems", read recently in London before the Institution of Electrical Engineers by W. Casson and F. H. Birch, of the Central Electricity Board, discusses the theoretical and practical considerations affecting protective-gear engineering. After reviewing the responsibilities and qualifications of protective-gear engineers the authors investigate a number of typical system fault conditions, giving methods of calculating fault currents and voltages, the relations between which are illustrated by vector diagrams. System abnormalities other than faults are discussed and attention is directed to their relation to protective-gear operation. The performance and correct application of protective gear are stated and a general outline of the work of commissioning the gear is given according to the type in use. Testing methods and testing equipment are described and consideration is given to protective-gear troubles and routine maintenance procedure. Finally, the paper discusses those features of protective-gear design, construction and layout which assist maintenance. The paper is based upon experience obtained during the last ten years with protective gear installed on the Grid system in Great Britain which, while having been designed primarily for peace-time fault conditions, has been found to give an overall fault performance of 92 per cent correct in 1940 when, due to war-time hazards, operating conditions were exceptionally severe.

Recent Earthquakes

THE Jesuit Seismological Association of Saint Louis, U.S.A., has determined the epicentres of several recent important earthquakes. From an analysis of twelve seismograms obtained at observatories throughout the United States, the earthquake of September 24, 1941, at 01h. 01m. 27s. U.T. is considered to have had a tentative epicentre at lat. 50·0° N., long. 158·3° W. This is in the Pacific Ocean, south of the Alaska Peninsula, and the focal depth of the shock is estimated by the Brunner depth chart to have been near 100 km. On the basis of reports from ten stations, the earthquake of September 25, 1941, at 17h. 48m. 49s. U.T., had its tentative epicentre at lat. 20·3° N., long. 155·1° W. This is in the Pacific Ocean, just a little to the north of the island of Hawaii. A third, and probably the most important of these three shocks, occurred on November 25, 1941, at 18h. 03m. 57s. U.T. It was recorded with very great ground amplitudes at observatories throughout the world (NATURE, December 6, 1941, p. 690). To obtain the epicentre of this earthquake, Edward J. Walter used the readings of seismograms from twenty-six observatories, mostly in North America and the Pacific Islands, and obtained a tentative epicentre at lat. 37·3° N., long. 19·1° W. This is in the north Atlantic Ocean, between the Azores and Portugal. Undoubtedly, if this earthquake had had an epicentre near any populated area, it would have caused widespread destruction.

Bibliography of Pharmacology and Chemotherapy

BEGINNING with Vol. 3 (1942) the name of the "Bibliography of Pharmacology" is changed to "Bibliography of Pharmacology and Chemotherapy". No change in scope is contemplated: "Chemotherapy" is added only to make the title more accurately descriptive. The publication is a reference list of current American and foreign literature relating to the action of known chemical compounds (natural or synthetic) on animal organisms and to therapeutic use of such compounds, including clinical investigations but not including routine clinical and case reports. The annual subscription rate is 3.50 dollars, or 2.50 dollars to members of the Friends of the Hooker Scientific Library. Further information can be obtained from the Hooker Scientific Library, Central College, Fayette, Missouri.

Regnier de Graaf, 1641–73

DR. H. R. CATCHPOLE, of the Yale University School of Medicine, has directed attention to the occurrence last year of the tercentenary of the birth of the Dutch physician and anatomist, Regnier de Graaf, who at the age of twenty-two wrote a treatise on the pancreatic juice and when thirty-one discovered the Graafian follicles of the ovary. De Graaf was born at Schoonhove on July 30, 1641, and died at Delft on August 17, 1673, at the early age of thirty-two. He was the son of an architect, and he studied medicine at the University of Leyden. Then he travelled into France, receiving a doctor's degree at Angers and at Paris, making the acquaintance of the savants of the time. Returning to Holland, he settled at Delft, married, and continued the researches for which he is remembered. Haller says his death was occasioned by a very heated dispute he had with Swammerdam.

George Martine

SIR D'ARCY THOMPSON has recalled in a recent article (*Scotsman*, Dec. 27) the work of the eighteenth-century Scottish physician, George Martine, who died in 1741. Martine went to the University of St. Andrews at the age of thirteen, and later proceeded to Leyden to study under Boerhaave; there he took his M.D. in 1725. He returned to practice in St. Andrews, and at the age of about forty was made fleet surgeon to Admiral Vernon for the Cartagena expedition. Smollett was a surgeon's mate in the same expedition, and Sir D'Arcy believes that his surgeon Macshane in "Roderick Random" was really Martine. Martine died of malarial fever when the expedition was in the Caribbean Sea.

Martine was a good mathematician and natural philosopher as well as a physician, and in Sir D'Arcy's opinion narrowly missed making some of Black's cardinal discoveries. In "De Similibus Animalibus" (1740) he discussed the effects on the circulation of change of magnitude in an animal, now known as the principle of similitude; in "De Calore Animalium" (also published in 1740) he dealt with the heat of warm-blooded animals, which he believed was due to friction of the blood on the walls of the blood vessels. He knew that the temperature of the skin of a man is about 97°, while that of dogs, cats, oxen and swine is higher and of birds highest of all. He wrote several papers on heat and the early history of the thermometers, and had a good notion of an absolute zero. His papers on medical topics included one "On Periods and Crises of Disease", while a paper on a tracheotomy performed in St. Andrews, including a description of a double cannula suggested by "one of our Ministers here" is printed in the *Philosophical Transactions* of 1730.

Cecil Peace Prize

A CECIL Peace Prize of £100, open to all undergraduates, without distinction of sex or nationality of any university or university college in Great Britain or Northern Ireland, who have attained the age of twenty-five on the last day of submitting essays, is offered for 1942. The subject is: "In what sense did the League of Nations succeed or fail?" The Prize for the 1941 essay has been awarded to The Hon. N. H. C. Bruce, Oriel College, Oxford; *Proxime accesserunt*, L./Cpl. R. James, University of Liverpool, and Miss Eileen Taylor, St. Hugh's College, Oxford. Further information can be obtained from the Secretary, University Bureau of the British Empire, c/o University College, Gower Street, London, W.C.1.

X-Ray Analysis in Industry

THE Institute of Physics is arranging a conference on "X-Ray Analysis in Industry" to be held in Cambridge during April 10–11. The purpose of the conference is to promote the interchange of knowledge and experience between those employing X-ray analysis (diffraction methods) in their work in different fields, and to arrange for further collaboration between physicists, engineers, chemists and others towards the solution of problems by its methods. The discussions, which will be based on papers included in the symposium already published by the Institute (*J. Sci. Inst.*, May and July, 1941), will be informal. During the conference, Sir Lawrence Bragg will deliver a lecture on "The History and Development of X-Ray Analysis". Further particulars can be obtained from the Secretary of the Institute of Physics, temporary address, University, Reading, Berks, to whom application for accommodation in Cambridge should be made before February 14 next.

Announcements

PROF. C. LOVATT EVANS, Jodrell professor of physiology in University College, London, has been elected an honorary member of the Sociedad Argentina de Biologia.

CAPTAIN N. H. HECK, chief of the Division of Terrestrial Magnetism and Seismology of the U.S. Coast and Geodetic Survey, has been awarded the degree of doctor of science by Fordham University, for his distinguished work in connexion with seismology.

Emulsification and Absorption of Fats and Paraffins in the Intestine

It has been shown by Frazer[1,2,3] that a fat, such as triolein, is only partially digested in the intestine by the pancreatic juice. Hydrolysis determines the path taken by the absorbed fatty material, the fatty acid fraction passing by the portal vein to the liver, and the unhydrolysed portion by the lymphatic route into the systemic blood and thence to the fat depots. This conception is contrary to the previously accepted hypothesis of Verzar[4] that the fat was completely hydrolysed, and the resultant fatty acid was carried through the intestinal membrane by means of a complex formation with the bile acids and resynthesized to fat again in the cells before being transported into the blood stream via the lacteals. The absorption of unhydrolysed fat raises a special complication, since triglyceride behaves physico-chemically very much like paraffins, which are not normally absorbed from the intestine. Furthermore, it is easy to show that bile acids or their salts form no complexes with either triglyceride or paraffin but only with fatty acid.

It was considered that in the intestine there was an ideal system for causing an emulsion of olive oil to be formed; there is present some oleic acid due to the action of the pancreatic lipase on the olive oil, some soda to form sodium oleate *in situ* on the surface of the olive oil globule, and cholesterol to keep the sodium oleate at the interface by complex formation (Schulman, Cockbain and Alexander[5,6]). This was proved by making a spontaneously forming emulsion of olive oil in water by dissolving 0·2 per cent of oleic acid and 1 per cent cholesterol in olive oil, and pouring the mixture into an $N/10$ soda solution. This emulsion was much better than one formed by pouring an olive oil – cholesterol mixture into a sodium oleate solution, containing an equivalent amount of sodium oleate as would be formed by the oleic acid and soda, added separately. Probably in the former case the sodium oleate is formed at the surface where it is required, while in the latter case an adsorption to the oil/water interface would have to take place; this requires time and a large artificially formed surface as produced in an emulsifying machine.

Further, it can be shown that in the intestine of rats which have been given a quantity of olive oil, strong emulsification of the olive oil can be seen, whereas in a rat that has been given liquid paraffin no emulsification is observed, but only the free oil, which has not been absorbed. It was therefore considered that the absorption of the olive oil by the intestine is brought about by the fact that the oil is emulsified, and that the droplets of $\frac{1}{2}\,\mu$ in diameter can be ingested by the brush membrane of the intestine. On this hypothesis, therefore, it should be possible for the intestine to absorb liquid paraffin, should the paraffin be in the form of an emulsion in the intestine. This was shown to be the case. If small quantities of oleic acid and cholesterol be added to the paraffin, which can then be emulsified in the usual way, and the emulsion injected into the duodenum, or if the mixture be given into the stomach and emulsification permitted to take place spontaneously in the intestine, strong absorption of the liquid paraffin takes place. This absorption was similar to that obtained for olive oil alone. In the control experiments negligible absorption of the paraffin alone took place.

The absorption of liquid paraffin by the intestine was demonstrated in rats by three methods: histologically, biochemically, and by chylomicrographs. Histologically, the staining of the paraffin oil droplets in the intestinal wall cells was most marked. These droplets, as seen in frozen sections, appeared to be of the order of $\frac{1}{2}\,\mu$ diameter. The control experiments with unemulsified paraffin showed no Sudan-stained droplets in the intestinal membrane cells.

Biochemically, the absorption of emulsified paraffin was found to be as high as 60 per cent of the quantity administered, which compared favourably with the absorption of olive oil in control animals over a similar time-period.

The chylomicrograph is constructed from counts of fat particles in the blood made under standardized conditions (Frazer and Stewart[7,8]). By serial investigation at 30-min. intervals the passage of absorbed fatty material in the blood stream can be observed. A chylomicrograph similar to that obtained with olive oil with a peak of 200 particles per field was found with good paraffin emulsions. Coarser paraffin emulsions containing no cholesterol gave a peak of 100 particles per field, and unemulsified paraffin only about 20–30. All these counts were from made systemic blood from the rat's tail and heart.

The interesting problem now arose as to how a paraffin droplet of $\frac{1}{2}\,\mu$ diameter could be absorbed by the intestine. A possible clue to this question might come from some unpublished work of Pantin and Schulman, who showed that nematocysts of sea anemones would shoot and stick when the nematocyst cell has been touched by some paraffin, but not when the paraffin has been made hydrophilic on the surface by the presence of fatty acid or protein. It could thus be supposed that the paraffin or olive oil will not stick to the intestinal wall unless the oil droplets have a hydrophilic coating as they have in the case of stabilized oil-in-water emulsions. Further, it might be supposed that the droplet must be of the size of $\frac{1}{2}\,\mu$ or of a smaller diameter before the membrane can ingest the particles on the amœboid or phagocytic principle. This particular dimension of the droplets is that which is found in stabilized emulsions.

The part the bile acids play in the intestine is not quite clear. It can be shown by the emulsion technique that the association of the bile acids is strong to oleic acid; this association is weakened with the bile acid salts, whereas no association can be established for the bile acids with olive oil or paraffin. Pantin and Schulman showed with the nematocyst experiments that the bile acid salts made the nematocysts all shoot spontaneously, whereas the other capillary active compounds, such as long-chain sulphate, amine and carboxylic salts, only cytolized the cells. The bile acid salts, since they form no complexes with compounds other than the fatty acids, do not lower the interfacial oil/water tension of these complex systems, as compared with the other capillary active compounds, and are, therefore, very poor emulsifying agents. Further, the bile acid molecule containing several polar groups cannot pack into the interface as compared to a normal straight-chain compound with one polar group. This is borne out in the poor surface-tension lowering properties of the bile acid salts.

The details of this work will be published elsewhere.

Toxic Effects of Certain Bacterial Metabolic Products on Soil Protozoa

THE chemotherapeutic value of the antibacterial substances produced by micro-organisms has attracted much attention in recent years. Very little is known concerning the effect of these antibacterial substances on Protozoa. For the past few years I have carried out work[1,2,3] on the selectivity of bacterial food by soil Protozoa, with special reference to amœbæ. In an attempt to correlate the non-edibility of pigmented bacteria, a suggestion[3] has been made that pigment formation by bacteria exerts a protective action against protozoal attack.

The extracted pigment from *Serratia marcescens*, *Chromobacterium violaceum* and a red pigmented bacterium 5654 (the characters of which are given by me[1]), when mixed with edible bacterial suspensions on an agar plating, apparently prevents the amœbæ from eating the edible food. Within a few days the amœbæ either encyst or die without destroying more than a few of them. Non-pigmented strains of *Serratia marcescens* are slowly but completely destroyed by amœbæ. The pigment of *Serratia marcescens* diffusing through agar has also a toxic effect on soil amœbæ and prevents them from eating edible bacteria.

Some interesting observations have been made on the toxic effect of the metabolic products of *B. pyocyaneum* on soil Protozoa. When the organism is grown on glycerol-peptone agar for 3–30 days, a chloroform extract of the bacterial growth, redissolved in water, is very toxic in strong concentrations to soil amœbæ, flagellates and ciliates, which are killed in a few minutes. At dilutions of 1/2,000 and 1/4,000, it takes 3–8 hours and 12–48 hours respectively to kill Protozoa, the effect at a given dilution varying with the type of protozoan. At dilutions of 1/8,000 and above, some types of Protozoa are killed within forty-eight hours while others are unaffected. Schoental[4] has studied the antibacterial agents present in cultures of *Ps. pyocyanea*, which include α-hydroxyphenazine. The chemically pure pyocyanin and α-hydroxyphenazine are less toxic to soil Protozoa than the above-mentioned crude chloroform extract. The chemically pure pyocyanin is slightly more toxic than α-hydroxyphenazine.

The more toxic nature of the crude extract is thus probably due to the fact that it contains other substances in addition to pyocyanin. When the crude chloroform extract of pyocyanin, dissolved in water, is passed through an *L* 5 Chamberland candle, the pyocyanin is adsorbed by the candle, and a light tea-coloured filtrate is obtained, the toxicity of which on Protozoa is increased by autoclaving at 15 lb. pressure for 15 min. The nature of this substance is being studied.

A fluorescent pigment, which is quite different from pyocyanin, obtained by growing *B. pyocyaneum* in liquid media, is also toxic to soil Protozoa.

A detailed study of the work carried out on the toxic effect of bacterial products on soil Protozoa will be published later, and it is hoped to extend this study to the effects of other antibacterial substances produced by micro-organisms on pathogenic and soil Protozoa.

A Useful Abnormality of the Pollen in a Pear

THE exceptionally low number of good seeds obtained when the pear variety Beurré Bedford is used as pollen parent in breeding experiments[1] led me to observe a series of developmental aberrations in this variety which may prove of value in producing new and improved forms.

The variety is a diploid ($2n = 34$), but, following normal meiosis, cell walls fail to develop between the four haploid nuclei, and thus the pollen mother cells are transformed directly into giant four-nuclear pollen grains.

Immediately before the first pollen grain mitosis these nuclei begin to fuse with one another, so that the following five types of mature grains, classified according to the number and constitution of the generative nuclei, are produced:

Types	$4x$	$3x+x$	$2x+2x$	$2x+x+x$	$x+x+x+x$
Percentage	81·5	9·3	6·9	1·9	0·4

The pollen grains of all these types germinate readily in culture (more than 90 per cent germination) and with more vigour than pollen from normal diploid and tetraploid varieties. The pollen tubes are almost invariably branched, although generative nuclei can be observed in only one of the branches. Such branching cannot be attributed to the multi-nuclear nature of the cells, since more than 80 per cent of the pollen grains have the vegetative as well as the generative nuclei single.

Growth of these pollen grains is also vigorous in stylar tissue and the tubes enter the embryo-sac in the normal manner[2], but very few good seeds are obtained[1].

In crosses with diploid and tetraploid varieties

B. Bedford gives progeny with the following chromosome numbers:

	$2x$	$3x$	$4x$	$5x$	B.B. gametes
$2x$ × B. Bedford ♂	7	—	4	—	x, $3x$
$4x$ × B. Bedford ♂	—	—	3	2	$2x$, $3x$
B. Bedford ♀ × $2x$	10	—	—	—	x
B. Bedford ♀ × $4x$	—	3	—	—	x

Thus on the female side gamete formation is normal while on the male side there is a strong selection of particular types from those provided by its irregular behaviour.

This behaviour affords us a means of synthesizing a wide range of new polyploid forms of pear by using Beurré Bedford as a male parent in crosses with existing varieties.

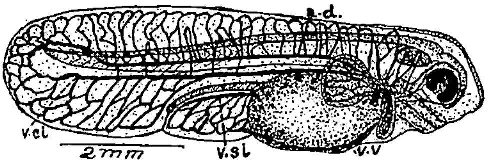
The Tail of a Fish Larva as Respiratory Organ

RESPIRATION through provisional organs is found in many tropical fishes. Rauther[1] has summarized this subject and Kryzanovski[2] has lately described the respiration in the teleostome fish embryos and larvæ. In cases where the circulation develops before the proper respiratory organs, Krogh[3] says that part of the animal surface functions provisionally as a respiratory organ. Capillary or lacunar systems of blood vessels are indicated by Kryzanovski as a respiratory system of certain Cichlidæ fishes, which have the anal or the dorsal fin slightly vascularized.



"TRAIRA" LARVA. *a.d*, AORTA DORSALIS; *v.ci*, VENA CAUDALIS INFERIOR *v.si*, VENA SUBINTESTINALIS; *v.v*, VENA VITELLINA. LIVING ANIMAL.

I have observed several larvæ, 6–7 mm. long, of the Brazilian fish called "Traira" (*Hoplias malabaricus*), the tail of which is largely provided with a compact vascular net. The blood proceeds from the heart by the *aorta dorsalis* (*a.d.*) and runs in the tail through a great number of capillary blood vessels forming many loops, thus increasing the respiratory surface. In this manner the preanal, anal and dorsal fins appear densely vascularized. The loops return to the *vena caudalis inferior* (*v.ci.*) and the *vena subintestinalis* (*v.si.*). Part of the oxygenated blood comes back to the heart by these capillary vessels; the rest of the blood runs to the heart through the vitelline vein (*v.v.*).

"Traira" larvæ are provided with thin jugular fins moving quickly. These fins also have a number of capillary blood vessels. Under the Greenough microscope the circulatory current can be seen running into the smallest capillaries distributed in an extremely thin vascular net. Some capillaries coming from the head and around the eyes also carry blood to the heart. Only rarely have I seen many flagellates on the tail surface, probably Bodo, commonly an indicator of the presence of oxygen.

None of the fish larvæ examined had either gills or the mouth completely formed.

Such a characteristic aspect shown by "Traira" larvæ is comparable only with that figured by Kryzanovski in *Acipenser stellatus*, but this fish does not possess a caudal vascular net so compact as that of "Traira" larvæ. Krogh, in his recent book, indicates the tail as a respiratory organ in the young Acara, but it was impossible to obtain more information about this interesting tropical fish on this matter.

Further researches on these lines are proceeding, and it is hoped to publish the details soon.

Mechanism of Kinetic Friction

FROM the recent paper by Morgan, Muskat and Reed[1], on "Friction Phenomena and the Stick-Slip Process", it is apparent that their ideas and experiments are progressing on lines similar to our own.

It has long been thought in this Laboratory that the Bowden and Leben[2] friction-measuring apparatus, in which a slider under elastic control presses on a plate which moves at constant velocity, shows by its 'stick-slip' motion merely that kinetic friction (F_K) is less than static (F_S); and we agree with Morgan, Muskat and Reed that Bowden and Leben did not give sufficient consideration to the dynamics of their system. It follows from the elementary treatment of oscillations with Coulomb damping, in which it is assumed that F_S is greater than F_K and that F_K is independent of velocity, that relaxation oscillations of the type shown by Bowden and Leben will occur (see Thomas[3] on "Vibrations Damped by Solid Friction"). It does not follow, however, that, if relaxation oscillations do occur, the above assumptions are true. For, provided the F_K-velocity curve falls rapidly, with increase of velocity over the lower ranges of velocity, relaxation oscillations of the same apparent form will be obtained; and without detailed analysis of the 'slip' portion of the cycle, and probably additional experiments, it is not possible to deduce from Bowden and Leben's papers, or others describing work with similar apparatus, any information regarding F_K, except that in general F_K is less than F_S.

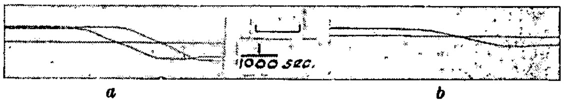

Fig. 1.

HARDENED STEEL SLIDING ON NICKEL LUBRICATED WITH NUJOL: *a*, PLATE SPEED, 0·01 CM. PER SEC.; *b*, PLATE SPEED, 1·0 CM. PER SEC.

It recently became necessary, with the use of an apparatus of the Bowden-Leben type, in measuring the coefficient of friction for lubricated and unlubricated metals in contact, to examine the system in detail. Records taken, with a high-speed camera, of the 'slip' part of the cycle (Fig. 1), together with those of the free oscillations, show subsidiary oscillations in the system which preclude accurate analysis of the motion. Experiments have also shown a marked decrease in amplitude of the 'stick-slips' with increasing lower plate speed (Fig. 2). It would follow, at first sight, from the simple assumptions above, that F_S decreases as the rate of wind up of the spring increases, and that F_K is constant over the whole range of speeds.

Actually, as already mentioned, no such deductions can be made without further investigation. Moreover, measurements show that during the 'stick' there is a slow creep back of the top slider, which increases as the lower plate speed increases. This implies that F_K is, at low velocities, not less than, but greater than F_S, rising to a maximum with increasing velocity, and then, to give the 'slip', falling rapidly; this would agree with an observation by Papenhuyzen[4] with rubber sliding on glass and road surfaces. In the present experiments, however, there is an inconsistency in that this rise in F_K is not shown when the plate speed is reduced to the appropriately low values. This anomaly, implying a progressive change in height—with plate speed—of the maximum of the F_K-velocity curve (top of 'stick', that is, apparent static value), may be peculiar to this instrument in so far as displacement is accompanied by twisting of the top slider relative to the lower plate; this may give enhanced adhesion at low plate speeds, as noted by Tomlinson, Thorpe and Gough[5], the effect decreasing as plate speed increases (that is, speed of twisting increases). The further analysis of these results, and the experiments now in hand to clarify the position, will be described at some later date, but it is apparent that the observations made with this apparatus previously published are superficial as regards fundamental information on kinetic friction.

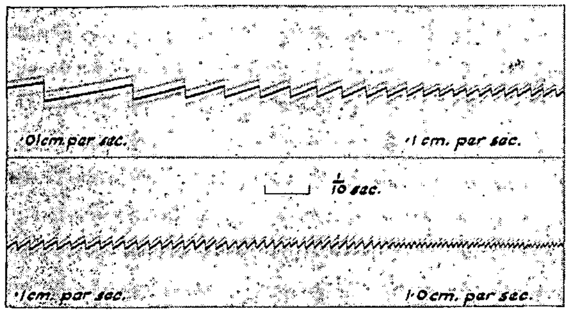

Fig. 2.

LEAD-ANTIMONY EUTECTIC SLIDING IN HARDENED STEEL (DRY).

Further to the considerations of the dynamics of the measuring system, two other points may be mentioned. (1) As yet temperature flashes of more than 30° C., during slip, have not been recorded, in agreement with the order given by Morgan, Muskat and Reed (50° C.). Some widely varying temperature distribution over the contact area is therefore necessary to make hot welding possible as part of the phenomenon. Further, it may be noted that the speed of 'slip', and therefore the temperature rise, will depend on the dynamics of the particular system; the 'stick-slips' are still obtained when the speed of slip is reduced to 1/100 of its normal value with this apparatus, suggesting that high temperature rise is not essential to the 'stick-slip' behaviour. (2) It has been suggested by Bowden and Leben[6], and Tabor[7], that the exhibition of 'stick-slips' is indicative of poor boundary lubrication. Apart from the difficulty of seeing why the mere fact of F_S exceeding F_K should imply poor lubrication, it has been found that smooth sliding can be obtained, using dry surfaces, at a value of F_K exceeding the whole range of 'stick-slips' for the same surfaces lubricated. Moreover, the damage during smooth sliding was much the greater. This friction result is corroborated by Morgan, Muskat and Reed, who have failed to correlate the presence or absence of 'stick-slips' with the values of F_S. It follows, therefore, that the above suggestion requires at least very careful qualifications.

Determination of Moisture

Several writers have recently discussed in Nature[1,2,3] methods for the determination of the moisture content of small samples of biological material. It has occurred to us that the method we have described[4] for the measurement of moisture in electrical insulating materials might be of great use in this connexion. In brief, the method consists of the removal of moisture from the specimen *in vacuo*, the moisture being retained in the specimen during the initial evacuation by cooling in solid carbon dioxide. The moisture removed on heating the sample to a constant temperature is then measured by observing the water vapour pressure produced at atmospheric temperature in a globe of known volume. Complete removal of the water is not attempted, but a graphical extrapolation is used to determine the total moisture content from the measured equilibrium water vapour pressure.

A trial of the method with biological material has been made, using small samples of egg white and yolk. Determinations were made using samples weighing only 30 mgm. and it was found that the yolk contained 48·6 per cent moisture and the white 82·2 per cent. The method has also been used satisfactorily for measuring the moisture content of honey. Even smaller samples could be examined, since the method is so sensitive; 1 mgm. of water vapour produces a pressure of about 4 cm. of oil in the present apparatus. The method cannot produce oxidation of the sample, since no oxygen is present. The temperature of the sample in the above tests was 120° C. but lower temperatures can be used for samples which might be unstable at such temperatures. In the original description of the method, measurements on paper at 0° C. were quoted.

HORMONAL INCREASE OF RESISTANCE AND ITS MECHANISM

By PROF. ERIK AGDUHR
University of Uppsala

INVESTIGATIONS already published[1, 2] have made it clear that pregnancies cause an increased cell vitality in the mother organism, and that they can even bring about a not inconsiderable organ increase there. It has also been found that the pregnancies give rise to a heightening of resistance to injurious factors[3]. A similar heightening of resistance is produced by normal sexual functions. In earlier publications[3] it has been shown how normal sexual functions in both sexes raise the resistance to a number of different toxic agents, as, for example, large repeated doses of activated ergosterine, different metal salts, alcohols, narcotics, paratyphus cultures, diphtheria toxin. The injurious factor most commonly used in my experiments was arsenic trioxide, and the most usual animals were white mice, though white rats and rabbits were also included in a number of experiments. All the animals received the complete basal diet. In most of the experiments the toxic agent was administered in proportion to the body-weight, and in doses increasing daily until the animals died.

Numerous experiments (1935 and later[3]) have made it possible to establish as correct the view already expressed in my first publication in this field (1931), that the results are conditioned by hormones. A considerable increase in resistance was obtained from giving œstrone (Ovex, Leo) and testosterone (testo-steronpropionate, perandren) to castrated animals, and Antex, Leo (gonadotropic, pars anterior, pituitary hormone, obtained from pregnant mares) to animals without normal sexual functions ('celibate animals')—an increase which, in some experiments, exceeded that which normal sexual functions (*m*) were able to set up.

In mice treated with colchicine, mated animals showed a much greater number of mitoses, *inter alia*, in the interstitial cells as well as in the follicular epithelium cells of the sexual glands than the unmated ones. This indicates a richer production of sexual gland hormones in mated animals[4].

The increase in resistance among the *m* animals was as a rule greater in the females than in the males. This appears to me to be due to the fact that in the latter, only the sexual association had a resistance-promoting effect, whereas the former have yet another such effect in their pregnancies.

Comprehensive investigations have shown that the resistance imparted by the pregnancies stands, at any rate to a certain extent, in proportion to the number of pregnancies passed through. As an example, it may be said that in an experiment comprising 35 mated females, 16 of them had been through more than half of the theoretically maximal number of pregnancies, while 17 had been through less than or half this maximum. All the animals were killed with arsenic trioxide solution with 0·05 per cent arsenic. The solution was administered at 0·1 c.c. per 20 gm. body-weight, and the dose rose daily at 0·02 c.c. per 20 gm. body-weight.

The result was :

$$D = \frac{M}{16} - \frac{M}{17} = 0{\cdot}0328 \pm 0{\cdot}00775 \text{ mgm. arsenic per gm. bodyweight}^{5}.$$

Here, therefore, we have a statistically significantly greater increase of the resistance, caused by a greater number of pregnancies among animals otherwise equal and comparable, belonging to the same experimental series[6].

Quantitative micromorphological analyses *inter alia* showed the occurrence of an important increase in number of the acidophil (eosinophil or alpha) cells of pars anterior of the pituitary body of mated females. As is well known, these cells produce a growth-hormone, which increases the vitality of the cells as well[7].

Statistical investigations have shown that married people live longer than unmarried ones, and that this increase of the span of life is more marked among women than men. Cancer of the breast and diseases of the heart are more frequent among unmarried women than among married. In my opinion there is no doubt that in the human being also, endocrine factors are the true explanations for this heightened resistance among married individuals, agreeing in principle with what the experiments with white mice have shown.

An association before puberty of females (white mice at an age of thirty days) with the opposite sex speeds up the setting in of puberty, also characterized by a retrogression of the thymus which starts earlier than it would otherwise. Compared with females which were admitted to cohabitation with the males at an age from about 175 days, the first-mentioned animals show a greater increase in resistance, probably most nearly due to the fact that the number of pregnancies they go through is greater not only absolutely, but also in relation to the length of the fertility period. Quite the opposite is found to obtain among the males as regards the gradual appearance of the resistance increase following an early and a late start respectively of sexual relations.

Study has been devoted to the mechanism at the appearance of the heightened resistance to arsenic trioxide, in which it has been shown that two systems of factors play a part. One system is set up by the sexual functions and the other by the pregnancies. The effect of both these systems is to a certain extent antagonistic with regard to the arsenic storage. The sexual functions, on account of an increased production of sexual hormones in both sexes and also a number of tested sexual hormones, cause an increased storage of arsenic in organs rich in ground substance or stroma tissues, and particularly in the skin. Females with a number of pregnancies that, reckoned per time unit, is percentually greater, have shown a slighter arsenic storage, at the same time as the lethal quantities of arsenic have been considerably larger reckoned in mgm. per gm. body-weight[8]. This effect is obtained by an increased function of the eosinophil glandular cells of pars anterior of the pituitary body. The hormone produced by these cells causes an increased vitality of the cells and as a consequence also an augmented excretion of the arsenic.

It would therefore seem that the heightened resistance which the normal sexual functions bring about is most nearly due to the fact that the increased storage in the ground substance or stroma tissues to some extent liberates the more sensitive and more important parenchyma cells from toxic influences. On the other hand, the pregnancies give rise to an increased cell activity, and, as a result, an increased excretion from the organism of the toxic substances.

This in its turn explains the smaller storage in larger numbers of pregnancies.

As the skin in particular has been the place where arsenic was stored, it has been studied in more detail, whereby it has been seen that sexual functions and sexual hormones bring about an obvious check to the spreading possibilities which the skin otherwise shows, and also that they give rise to an increase in the thickness of the corium and a distinct increase of non-ether-soluble dry substances reckoned per unit skin surface. These results all seem to explain the increase of arsenic storage in the skin of both *m* and *u* animals dosed with Antex, Leo, or castrates which have been given Ovex, Leo (=œstrone), and testosterone respectively.

The expenses of this investigation were defrayed by grants from Stiftelsen Thérèse och Johan Anderssons Minne, The Caroline Institute, Stockholm, and from the Regnells fund of the University of Uppsala.

PERMIAN FOSSILS FROM THE EASTERN HIMALAYA*

IN 1849, having traversed the igneous and metamorphic rocks of the Sikkim Himalaya, Joseph Hooker discovered a limestone containing fragmentary organic remains. The fossils were thought to be nummulites, but afterwards they were shown to be crinoid ossicles of uncertain age. Fifty years later, E. J. Garwood found that the high range bordering Sikkim to the west of Hooker's locality was formed of thick, altered limestones containing crinoid remains, and he considered that these limestones, probably Silurian or Carboniferous in age, were the westward extension of Hooker's limestone. On the other hand, Henry Hayden, in 1907, mapped the rocks east and north of Hooker's locality and proved a sequence from Jurassic to Eocene; he suggested that Hooker's limestone might be the equivalent of one of the Jurassic limestones found by him in southern Tibet.

The actual locality of Hooker's find was not revisited until after the 1933 Mount Everest Expedition. On this occasion small collections of fossils were made which form the subject of this paper, one from Hooker's locality, another from a horizon in the Lachi Hills near by, and a third from erratic material derived from the Mount Everest Limestone Series, which includes the limestones of North Sikkim first described by Garwood. The valuable results obtained from this scanty and badly preserved material, which was collected by the present reviewer, are a tribute to the skilful way in which the modern palæontologist works, extracting much of value from very little.

In the Lachi Hills overlooking Hooker's locality, an outcrop of the highly characteristic Mount Everest Limestone, which forms the summit of Mount Everest, was found to be overlain by quartzites, shales and pebbly sandstones which were named the Lachi Series. Brachiopods from a horizon in the Lachi Series are shown by Dr. Muir-Wood to include *Marginifera himalayensis*, *Spiriferella rajah* and *Neospirifer moosakhailensis*, and a valuable discussion of the affinities and distribution of these and some other species is provided. On the basis of the brachiopod fauna, Dr. Muir-Wood shows that this fossiliferous horizon in the Lachi Series is equivalent to the Productus Shales of Spiti and the Zewan Beds of Kashmir; she also shows that it is probably of the same age as the upper Productus Limestone of the Salt Range, although of a somewhat different facies. The relation of these Tethyan deposits to the Permian succession in Russia is considered and the conclusion reached that this horizon of the Lachi Series is Upper Permian. Molusca and Bryozoa, described by Dr. Oakley, support the hypothesis of the Upper Permian age of the beds.

The few organic remains from Hooker's limestone, only a single block of which could be brought back owing to transport difficulties, indicate a probable Permian or Triassic age. The fossils include a new species of Solenopora, the first species to be described from the Permian of a genus which ranges from the Lower Palæozoic to the Jurassic. To his description Dr. Oakley appends a valuable discussion on the nature of the Solenoporaceæ, of which the algal affinities, although usually accepted, have been questioned in recent years by several authors. Dr. Oakley definitely rules out the Hydrozoa, and on the whole favours the algal view.

The thousand feet or so of the Lachi Series lying below the Upper Permian horizon consists first of pebble beds and then of shales and quartzites. Below these lies the Mount Everest Limestone Series, an important rock group of the Eastern Himalaya, the age of which has not yet been directly established. A few fossils, including immature rugose corals, indeterminate brachiopods and a new species of Straparollus collected from shales below the pebble beds are described by the authors, but they provide no precise estimate of age. Nor can the fragmentary fossils from the Mount Everest Limestone itself give any satisfactory evidence for the age of that horizon. However, the authors attempt to estimate, by means of lithological comparisons, the age of these pebble beds, which include horizons in which pebbles several inches in diameter occur in a matrix of silt grade. This unusual lithology led J. B. Auden to liken these rocks to the Blaini tillites. If this correlation be accepted, then, as Dr. Muir-Wood shows, the pebble beds would be Upper Carboniferous in age and the Lower Permian would be missing on Lachi. As a corollary the age of the Mount Everest Limestone Series would be Lower Carboniferous or even earlier.

It is considered that too much assurance has been placed in the tentative lithological correlation of the pebble beds; the authors even go so far as to state that the horizon is a glacial boulder bed (p. 59), which is certainly an overstatement, so far as present evidence goes. It would seem to the reviewer quite as probable that there is no non-sequence on Lachi, that the pebble beds are Lower Permian in age, and that the Mount Everest Limestone Series is somewhat younger than is indicated on the assumption that the pebble beds are equivalent to the Blaini tillites. Providing, however, that arguments based on the possible glacial character of the Lachi pebble beds are regarded as no more than tentative, then the authors have done a service by working out the full implications of such a hypothesis.

These less secure deductions do not in any way obscure the main conclusion of the authors, that an Upper Permian horizon occurs north of the Himalaya in Sikkim. This provides a valuable *terminus ad quem* for dating the Mount Everest Limestone Series, a highly characteristic lithological unit, which should one day be a most valuable guide in unravelling the structure of the Eastern Himalaya.

A PROPOSED REFORMED MONETARY SYSTEM

AN interesting anonymous pamphlet designed to propose a reformed monetary system consistent with the requirements of post-war trade and economic intercourse between nations has recently been published*.

The author begins by saying that it will be indispensable after the War for nations which must have large exports in order to avoid the dislocation of their internal economies to find outlets for these exports, even if the recipients are not in a position, at any rate for the time being, to repay on a commercial basis with exports of their own. He concludes that it will be necessary to maintain control over the foreign exchanges for a period after the War, and for exports to be made on a basis which will give the exporters the alternative of receiving payment in goods or not being paid at all, as it would be clearly foolish to begin again the practice of piling up unpayable debts.

Then the author sets out proposals for the structure for a permanent post-war system of international trade. This he proposes to anchor to two forms of stabilization—stabilization of the internal price level in each country, measured in terms of the average general level of prices, and stabilization on a permanent fixed basis of the rates of exchange of the moneys of different countries. Having done this, he proposes to conduct all foreign trade by what amounts to an international clearing system, bilateral in the main but with provision for multilateral arrangements, and he suggests that all adverse balances not cleared by payment in goods to the creditor country within a period of seven years should be merely cancelled. Nations would then have no incentive to seek to export more than they are prepared to import, and would be in a position to adjust their economies to either a high or a low level of foreign trade actively.

It is clearly impossible to offer any effective criticism of these problems in a brief note. All that can be said is that the pamphlet sets forth cogently the shortcomings of the existing financial system, but slides much too easily over the difficulties inherent in either price stabilization or permanent exchange stability—much more over the difficulties involved in a combination of these two systems.

AIR-RAID DAMAGE AND ELECTRICITY SUPPLY

RECENT articles in the *Electrical Review* disclose the steps which have been taken to overcome air-raid damage to the properties of electricity supply undertakings, and the measures taken to restore supply. Without giving away vital information to the enemy, it may be said that, of the very large number of bombs dropped during a period of twelve months, some have inevitably fallen on or near power stations. Thanks to the design of the modern power station and the special precautions taken against blast and fire, the actual damage has generally been superficial. One of the newest stations in Great Britain, for example, which received a direct hit on the boiler house roof, sustained no damage that a few bricklayers and concreters could not make good in a few weeks, and the plant itself was unscathed.

An interesting and noteworthy experience arising from raids is that in the older types of buildings, damage appears to be limited to wood-supported roofs, and it is recommended that roofing be as thin as possible. The incendiary bomb will then pierce the roof and burn harmlessly on the concrete floor below, glancing off machinery, which should be suitably protected to ensure this. In this connexion "Durasteel", which has been used for the protection of switchboards and other vital apparatus and machinery, has fully justified the claims made for it. Several instances have been observed in which valuable plant has been saved by its use, the only noticeable damage to itself being discoloration.

Though incendiary fires in substations are uncommon it is desirable, in the interests of the safety of A.F.S. personnel, that the latter should notify the undertaking if fires occur adjacent to and threatening any of its property, as the A.F.S. is not normally provided with the necessary foam apparatus for dealing with burning transformer oil and outbreaks among live gear.

The greatest amount of damage experienced has been, not unexpectedly, that caused by bombs to underground cables. Experience has shown, however, that paper insulated, lead-sheathed and armoured cable stands up to very severe damage, irrespective of voltage, one instance occurring where only the electric cables supported a damaged bridge.

Numerous instances have occurred where cables, depressed and twisted many feet below the laid level, have not failed. Examination has revealed that sometimes, though not always, the stretching of directly laid cables has been confined to the length in the crater, and has not extended to any appreciable length on either side, slack in adjacent manholes having frequently been sufficient to prevent damage to joints. Cables laid in ducts have been pulled along the duct towards the crater, joint wipes being torn away from the lead sheath, often two or three manholes away. This pulling sometimes extended for

300–400 yd., and as many as three straight-through joints in series have been pulled out, the cores occasionally being broken inside the lead sheathing.

The restoration of supply has been much simplified by the existence of the grid and by the commendable foresight shown in providing a pool of apparatus upon which undertakings may call in emergency.

Incidentally, while it is essential to restore supplies as soon as possible, this does not mean that personnel should take unnecessary risks or attempt feats beyond their powers of endurance. There is a scarcity of trained engineers and it is foolish for them to risk their lives unnecessarily during raids, particularly men fully trained in the layout of networks. It is a great mistake to rush every available man to the scene of the damage, and to have too many of them at the same spot where they might all be put out of action by a single bomb.

One mitigating feature of the widespread bombing in some districts has been that it has assisted substantially in the change-over from D.C. to A.C.

Should property be demolished and the distributor damaged or severed in a crater, supplies may be restored by temporarily pot-ending the cable ends at each side of the crater, and making alive both ways. In the event of debris preventing access to the cable in the crater, the cable may be excavated and cut at points remote from the crater and pot-ended in the same way. One undertaking has adopted the unique expedient of dropping a new section of distribution cable in the crater, filling up around with cement and making permanent joints at the ends. When the work of clearing up the crater is nearly complete, an empty duct is laid in case the cement encased cable should fail at a later date.

Another ingenious example may be mentioned, in which all the high-voltage cables of two substations were hit by high explosive bombs. In order to restore supplies, temporary cables had to be run across a wide main road clear of the crater and other services involved. The road consisted of granite sets laid on 9 in. concrete, and as time could not be spent in breaking up the wide main road, about five rows of granite sets 7 in. deep were removed, the concrete road beneath remaining undisturbed. Wooden rails (4 in. × 3 in.) were laid in the sides of the trench, and 8 in. × 3-in. boards as long as the trench width were laid across to form a wooden bridge over the five 0·20-sq. in., 6·6 kv. cables required. The top boards were covered with earth, and main-road traffic passed over this run for many weeks. Perhaps even more effective is the digging of the smallest possible trench, running in armoured cable, and filling in solid with cement.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public.)

Monday, February 9

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 3 p.m.—Sir Malcolm Watson: "Geographical Aspects of Malaria".

Tuesday, February 10

Illuminating Engineering Society (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 2.30 p.m.—Short Contributions on Problems in Illuminating Engineering of the Present Time and in Post War Reconstruction.

Wednesday, February 11

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mrs. Darcy Braddell: "The Post-War Home—its Interior and Equipment". 5: "Common Sense in Furniture Design".

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 2.30 p.m.—Dr. Philip Hamill: "Prescribing in War-Time".

Physical Society (Colour Group) (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Annual General Meeting. Dr. W. D. Wright: "Research on Colour Physics at South Kensington, 1877–1942".

Society of Chemical Industry (Food Group) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. N. W. Pirie, Dr. T. Moore, and others: "Green Leaves as a Source of Protein and other Nutrients".

Thursday, February 12

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Dr. C. H. Waddington: "Some Biological Discoveries of Practical Importance".*

Friday, February 13

Royal Society of Arts (India and Burma Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. A. J. Gibson: "The Story of Lac".

Royal Astronomical Society (at Burlington House, Piccadilly London, W.1), at 4.30 p.m.—Anniversary Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Headmaster—The Clerk to the Governors, Rutlish School, Merton, London, S.W.19 (March 14).

Teacher of Mathematics (man or woman)—The Principal, South-West Essex Technical College, Forest Road, Walthamstow, London, E.17.

WELFARE AND TRAINING OF YOUTH

THE notable speech of Mr. R. A. Butler, President of the Board of Education, to a National Defence Public Interest Committee on December 10 is one of the indications which appear from time to time that the essential part of education both now and later has been realized. Mr. Butler claimed that his department is becoming recognized as the great national department of State for the training of the young. He gave the assurance that no further inroads on the teaching profession are contemplated at present, and he hopes the situation will never demand them. He viewed the registration of boys and girls of 16–18 years of age under the new National Service Act as a step towards building the arch from 14 to 18, and local authorities are being asked to do all they can to increase the facilities for training and service for boys and girls of 14–16.

These steps are not intended to take the place of the Fisher plan for continuation schools, but the scheme should accustom young people to the idea that in these early years the path to manhood and womanhood lies through knowledge and, broadly, citizenship. Mr. Butler indeed linked the scheme up with the idea of a new social charter, with its Bill of Duties as the counterpart of the Bill of Rights, which has been voiced in several quarters both in Great Britain and in the United States. From early youth, he said, the young citizen should learn that there must be acknowledged duties to be performed by the individual for the community, which should confer certain rights and privileges in return.

Mr. Butler's speech is the more encouraging to those who believe that the care of the children is the concern of the nation and that the welfare and training of youth are matters of supreme importance at all times because of the comparative neglect of education in the attention which has already been focused upon reconstruction. Despite the general recognition that the education of public opinion must be a prelude to effective action in almost every field, that has been viewed as mainly a matter of preparing opinion for change through some measure of adult education. There has been little indication of the conception of the education of the adolescent as part of a grand design embracing every aspect of life. The Minister of Labour has indeed already spoken in similar terms of the plans being initiated for the training of young people, and there is real promise in the evidence that Mr. Bevin and Mr. Butler are working together. Such co-operation should create the links between technical training and industry and commerce of which Mr. Butler spoke, and which are essential in the interests of both the individual and the nation.

Equally vital is the attention to voluntary training which will accustom young people, as Mr. Butler said, to the idea that in their early years the path to citizenship lies through knowledge, work and service. Inspired leadership should turn the eagerness of the juveniles to play their part in the war effort into channels which will fit them to play an equally or even more important part in the tasks of reconstruction which lie beyond. It is this vision of the future of education that is pregnant with possibilities in reconstruction, and a notable article in the admirable series on our problems of reconstruction running through the *Round Table*, which is concerned with the future of education, has particular claims on the attention of the scientific worker.

Directing attention to the part which science—in the Latin sense of the word and not the narrow meaning to which we usually restrict it—has played in stimulating the educational developments of the last seventy years, the *Round Table* points out that in a world where life is increasingly based on knowledge, the uneducated man is useless or dangerous. He is no less incompetent as a soldier or citizen than as an engineer. The need to train the intelligence of all, in order to live in a civilization where as much intelligence as possible is required, sufficiently explains the recent development of education and why such development must continue.

Some lines of further development have been indicated in the Hadow and in the Spens Reports, and the creation of a democracy which can enjoy and sustain the new order of society foreshadowed in the Atlantic Charter depends on our implementing such proposals. That democracy cannot be created if education for the vast majority stops at fourteen, or if we fail to give them the right kind of education. The question of the content of education and how it is to be given is the unsolved educational problem of to-day.

In any scheme of national education we must provide, as at present, for two great classes—the few and the many. The composition of the first class will no longer be the same as at present, for it should be recruited from the whole nation, without distinction of birth or wealth, and should consist of those whom the community chooses to be its leaders because of their fitness to lead. The selection of this class will, in fact, be one of the most difficult problems for society, involving as it does one of the gravest dangers to education. Already the competitive examination system is corrupting the disinterestedness which is the essence of all good education and without which liberal education is impossible.

If we can deal with this problem and at the same time remove the grave defect of our newer universities emphasized in two recent books—that they teach rather than educate—we have still to face the larger problem of the higher education of the many. Here everything remains to be done, and no one can suppose that the mere implementing of the provisions of the Fisher Act will provide a solution. At the age of fifteen or sixteen education has only commenced; it has certainly not reached its goal. Education is intended to be used in life, and its meaning and importance cannot be apparent to an adolescent or even to an undergraduate who has seen nothing of life. It is this fact that gives value to part-time education for the adolescent, and to adult education, which gives men and women engaged in the ordinary business of life the opportunity to think about it systematically.

The article in the *Round Table* suggests that the time has come for the lessons learnt during the last forty years through the experience of the Workers' Educational Association to be applied to other sections of the community, as has already been done elsewhere in Europe. While, however, such experiments deserve close study, and notably the Danish People's High School, we must beware of merely copying other systems. Education should be inductive and clinical, based on a study of the 'patients', as well as deductive, and if we are to achieve that essential element in post-war reconstruction, as educated people, we must bring imaginative insight to bear on our problem, creative thought as well as administrative ability and energy. We must plan our educational system not merely to include refresher courses for teachers, medical men, scientific workers and other professional or specialist workers, but also to keep the human mind of the whole people growing and alive, giving them an opportunity of systematic study and a chance to think methodically about life when they have far more to think about than they can have at school or university.

Leaving on one side for the present the question of the part which the university and the secondary school have to play in such a frame-work of education, with its emphasis on education rather than instruction or teaching, there must be considered these three elements which are essential in any education adequate to the needs of to-day. All men need to make a living and the best that conditions permit. All have to live in a society and all need a scale of values, a sense of what is first-rate, in life as a whole, and so far as is possible, in its many provinces. To meet these needs education must provide a vocational, a social and a spiritual element, and it must do this not for a limited class but, in different ways, for every citizen.

Of the vocational element it need only be emphasized here that a society should give its educated members not only specialist knowledge but also some perception of the general conditions and possibilities of modern civilization, and a sense of the importance and uses of the techniques essential to it. It is a knowledge of science in this sense, indeed, that should form part of the education of every citizen and not of the specialist alone, just as it is the wide vision and sense of perspective implied in such a general conception that should correct the narrow specialism which has often warped the development of the scientific worker himself and hindered his participation in the work of the community. To that, indeed, a fuller corrective is the social or political education of which, largely under the pressure of the competitive examination system, he has so often been deprived.

Some training in the art of governing and, still more, of being governed; in independence and in respect for authority; individuality and team-work; self-assertion and self-discipline and self-sacrifice; initiative and subordination: the value of these becomes more apparent with every passing day of war. Their value will be no less when the nation turns once more to the tasks of peace, and they are an essential part of the education of every citizen, whether he occupies a scientific, technical or administrative position or any other, just as some understanding of general science in the broad sense should make up part of his equipment for living in this modern world. The registration of boys and girls of 16–18 under the National Service Act can serve no more useful purpose than that of implementing this education in citizenship which certain institutions such as the Scout movement and the Youth Groups themselves are already imparting.

If we must discover new ways or forms for extending social education it is important that we should utilize to the full existing agencies and the foundations already laid. The *Round Table* article emphasizes the value of the public, or as it should be termed the residential, school, in training in the principles and practice of living in a community. This opportunity must not be thrown away, but the residential school, coming under the ultimate, though not necessarily direct, control of the Board of Education, should be open to every class in the community, and the right to entry should be based on merit, assessed not merely in terms of intellectual ability but also of character and personality. The further opportunities afforded by the growth of school camps, the development of the Youth Movement and of any form of national service or conscription which may persist after the War must also be seized for this education in citizenship and to promote mutual understanding between the different classes of society and thus to strengthen the national unity.

The third element is the most neglected and at the same time the most important and most difficult branch of education. Upon this, which for want of a better word may be termed spiritual education, the quality of our civilization, its standards, its sense of values depend. Without it we shall lack the driving force to carry through any adequate programme of reconstruction, national or international, which will make it endure. Knowledge or science, indispensable as they are in the framing of wise and impartial measures, are not enough. They cannot supply that habitual vision of greatness which, in Prof. Whitehead's phrase, is essential for moral education. They will not supply the driving force, the right standards, values and ideals without which no enduring social order can be built.

Difficult as this task must be, we must not be content with any system of education which does not give men both the chance of seeing the vision of greatness and of practising the virtues. New sources of that vision of greatness may need to be, and indeed are being, discovered. They can, indeed, be found in the quest of truth and the highest traditions of science, as in other fields of human activity, the Greek and Latin classics and in the Christian ideal and tradition. It must never be forgotten that science, economics and sociology can do no more than provide the framework of our society and satisfy its material needs. It is the vision and sense of values that spiritual education imparts that hold society together, supply its driving force and preservative against corruption. No pre-occupation, therefore, can excuse failure to place the spiritual element first in our system and to ensure that the vision of greatness from whatever sources it springs is available to all and not merely to the privileged few. The discussion on Science and the World Mind at the Conference on Science and World Order demonstrated that men of science are already thinking deeply about these problems, and they will be grateful for the evidence that Mr. Butler no less than his predecessor at the Board of Education is giving such close attention to the fundamental problem in all reconstruction—that of developing citizens, young or old, who can first reconstruct themselves.

PROGRESS OF GEOMAGNETISM

Geomagnetism
By Prof. Sydney Chapman and Prof. Julius Bartels. (International Series of Monographs on Physics.) Vol. 1: Geomagnetic and Related Phenomena. Pp. xxviii+542. Vol. 2: Analysis of the Data, and Physical Theories. Pp. x+543–1050. (Oxford: Clarendon Press; London: Oxford University Press, 1940.) 63*s*. net.

"THE earth itself is a great magnet." So wrote Dr. William Gilbert, fellow of St. John's College, Cambridge, nearly three and a half centuries ago. The detailed geographical determination of the nature of that magnetism, and the attempts to identify its origin, have since attracted much effort and friendly international co-operation. But, substantially, Gilbert's challenging statement still remains something of a mystery. For while much is now known of the origin of the small, but significant, periodic components of the earth's magnetic field, the genesis of the much greater quasi-permanent components continues unexplained.

The fundamental problem of the earth's main field is not rendered easier by the fact that that field is slowly changing. It is true that it does not change much in a human life-time, but, within astronomical and geological scales of time, the variation must be considered very rapid indeed. The direction of the magnetic north in England has, for example, changed by about 30° since Gilbert's time, while there are certain places on the earth's surface where the intensity of the magnetic field has altered by about 10 per cent during the last half-century. As a result of the early analyses of Gauss and Schmidt, it was established that the greater part of the earth's external magnetic field is due to causes operating beneath its surface. In fact, the earth behaves very much like a uniformly magnetized sphere with its magnetic axis making an angle of $11\frac{1}{2}°$ with the geographical axis of rotation. But the average intensity of magnetization has to be regarded as very much greater than that of the ordinary crustal rocks so far examined. To account for this is the central problem of geomagnetism.

Fortunately it is only the problem of the semi-permanent magnetism of the earth which proves so intractable. The transient changes of magnetism, which are to be noted during a period of time measured in hours, are not so unaccountable. They are known to be due to causes operating outside the earth's surface, as was also shown by the Gauss-Schuster analysis. They are superposed on the slow secular variations of the main field and may be divided into two classes: the regular solar and lunar diurnal variations and the more erratic variations characterized as magnetic storms. Both classes of variations are found to vary in intensity through the sunspot cycle.

Since, so far as we know, magnetic matter does not exist in the space round the earth, the primary part of these transient magnetic changes is probably due to electric currents. According to the bold speculation of Balfour Stewart, advanced in 1882, such currents are to be attributed to dynamo action in the earth's upper atmosphere. Now the essential feature of a dynamo is that it contains an electrical conductor moving in a magnetic field. The magnetic field is already provided by the earth, and Balfour Stewart suggested that the electric conductor is the rarefied upper atmosphere itself, which is made to move periodically across the magnetic field by the tidal and thermal action of the sun and the moon. That Balfour Stewart was correct in the essential postulates of his theory has been proved in experiments carried out in Great Britain. Thus, radio experiments in 1925 showed that the upper atmosphere is permanently ionized to a marked degree, while, twelve years later, similar experiments disclosed quite unexpectedly large tidal motions of that conductor resulting from the gratitational influence of the moon. Further evidence showing the connexion between ionospheric events and the ephemeral changes of terrestrial magnetism has been obtained in the study of ionospheric phenomena through the sunspot cycle. Radio experiments have shown that, at certain levels, the electrical conductivity of the upper atmosphere increases by about 50–60 per cent from sunspot minimum to sunspot maximum. During the same period there is a corresponding and equal enhancement of the solar diurnal variation of the earth's magnetism. By the same radio technique it has been further shown that this remarkable change in the ionosphere is caused by what may be as much as a 150 per cent increase in solar ultra-violet radiation.

But, although great progress has been made in disclosing the nature and identifying the causes of these transient variations of the earth's magnetism in work carried out since the nineteenth century, there has not hitherto been available any up-to-date account of such recent progress. In this book, "Geomagnetism", we have, however, the most satisfying fulfilment of this need. Those who know the subject would have chosen no other authors for its *magnum opus*. In zealous devotion to the subject over a period of many years, each has enriched our knowledge of both the nature and significance of the temporal magnetic variations; while Prof. Chapman's theoretical studies of ionized layer formation have greatly assisted those ionospheric physicists who have used the radio wave as a supplementary tool in exploring the nature of the upper atmospheric dynamo.

The two substantial volumes into which the work is divided cover the subject both widely and closely. The first volume contains an exposition of the magnetic facts, as gleaned from years of observation, and also includes briefer, but up-to-date, accounts of related subjects such as earth currents, auroral phenomena and ionospheric characteristics. The second volume is in two parts. In the first there is a most illuminating description of the mathematical apparatus which has been devised, much of it by the authors themselves, for use in the analysis of such complicated phenomena as result from the simultaneous influence of the sun and moon on the terrestrial atmosphere. In the second part of the volume there are expounded the physical theories which have been evolved to explain the facts as more simply revealed by such mathematical analysis. The two volumes, which are generously illustrated both by diagrams and plates, together include about a thousand pages of text and are very well furnished with bibliography and indexes. Particularly useful to the research worker will also be the tables of long series of magnetic and solar data brought up to the year 1937, with convenient spaces for the inclusion of later values.

Distinguished and scholarly in treatment, "Geomagnetism" will assuredly become a classic. Its publication has instantly increased the already considerable debt which workers in this and allied fields already owe to its two authors.

E. V. Appleton.

RAW MATERIALS

Those Raw Materials

An Introduction to the Study of Raw Materials. By C. A. Ward. Pp. 392. (London: George Allen and Unwin, Ltd., 1941.) 15*s*. net.

DESCARTES, it will be remembered, resolved to seek happiness by limiting his desires rather than by attempting to satisfy them, thus setting himself against the grain of common human endeavour. In these times, thanks to science, invention and advertising, our needs have multiplied like the seed of Abraham, and although some of them appear superfluous, or even harmful, many can be ethically justified on the score of self-preservation or self-development.

Very early man seems to have thrived on a dietary of berries, eggs and shellfish, and on clothing made of leaves and of the bark of trees; his heirs have scoured land and sea to find and exploit materials that administer to their well-being, and when frustrated they have fought—and still fight—for possession or control of them. The spirit of adventure, now believed to be on the decline, and the instinct of acquisition, still very much to the fore, have brought within range an almost untold wealth of raw materials which, when used rightly, add to the sum of human happiness, but, when used wrongly, lead to envy, hatred, masochism, sadism, and their sequel—war. Unfortunately, though there is seeming abundance for all, the will to dominate and possess has operated to alienate much of the world's natural wealth for the possession and enjoyment of the few, and this process has been assisted by the extremely haphazard way in which raw materials are distributed over the earth's surface (air, and to some extent water, excepted). That is not the fault of man. Nature—personified as a woman, somewhat unchivalrously to the fair sex—does not, like the moon, always show the same face to beholders. She can be exceeding fair, but she can be red in tooth and claw; generally she seems to be supremely indifferent to human welfare: as callous as was Herod to the Holy Innocents, or is Hitler to the Jews. The teleological doctrine, which *reads into* Nature a benevolent purpose, has now joined the scrap-heap of discarded wish fulfilments, and virile folk have come to realize that man is largely the master of his own fate: it is he alone who can smooth out some of those grosser inequalities of natural wealth and human endowment that undermine men's sense of security and lead to bitterness and strife. The Atlantic Charter has done well in postulating equal access to raw materials as a *sine quâ non* of a lasting peace.

Mr. Ward's introduction to the study of raw materials gives a good idea of their range and their uses; except when he wanders off into electronic theory, his treatment is entirely factual, consisting mainly of short notes and brief descriptions. Its main defect is that, with the exception of the chapters on coal and petroleum, it ignores the very important economic background; there is no discussion of rates of exhaustion and probable lives of mineral deposits, of improved means of extraction and conservation, or of geographical distribution in relation to marketing; and there is no map. On the other hand, much space is devoted to "metallurgical treatments as applied in the final preparation of metals", and to materials which cannot be accurately classed as 'raw'. Thus he devotes two chapters to chemical products, among which are included many intermediate substances, as well as finished products like dyestuffs, explosives, lead compounds, synthetic rubber and artificial silks. But little consideration is given to those ubiquitous raw materials, atmospheric nitrogen and oxygen, and water, which in recent times have been used more and more by the chemical industry. The future importance of the exhaustion of supplies of rock phosphate is ignored, as also are the possibilities of using sea-water as a source of commercial magnesium, potassium and bromine, and clay as a source of aluminium.

Criticism must also be extended to certain defects in literary style. Sir A. Quiller-Couch's lectures on "The Art of Writing" are still largely ignored by technical writers. Among the stylistic sins he denounced was the use of circumlocutory and redundant expressions, like 'in the case of', 'in connexion with', and 'as regards'. In the book under review the first of these occurs hundreds of times, and 'in the very first place' is a frequent substitute for 'first' or 'firstly'. The schoolboy error of referring to one thing, or to the last of three or four things, as 'the latter', disfigures many sentences. The title also savours of 'journalese', and in conformity with it the author overdoes the journalistic 'while', reminding one of A. P. Herbert's example: "The curate read the lessons while the vicar preached the sermon".

Books on scientific and technical subjects intended for the general reader are notoriously difficult to write. The first consideration for an author is to 'remember the reader' and adapt his style to the class of reader he has in mind. For the reason just mentioned, Mr. Ward's book cannot be recommended for use in schools, and the serious student will find it too fragmentary and too lacking in insight to meet his purpose. It will probably appeal most to the middle-aged man who wishes to rub up and extend the knowledge he acquired long ago; he will find it especially useful in reading company reports and similar 'literature'. One cannot help feeling that the author has lost an opportunity to write a book of real human interest, one that touches life at many points besides the purely technical. When he is asked to revise the present edition, perhaps he will try to convert his own 'raw material' into a finished product.

E. H. TRIPP.

INDUSTRY AND ITS HAZARDS

The Analytical Chemistry of Industrial Poisons, Hazards and Solvents

By Dr. Morris B. Jacobs. (Chemical Analysis, Vol. 1.) Pp. xviii+661. (New York: Interscience Publishers, Inc.; London: H. K. Lewis and Co., Ltd., 1941.) 7 dollars; 42*s*.

AT the present time, when the future of Great Britain and the very lives of our people depend upon the output of industry, the safeguarding of the health of industrial workers is a matter of supreme importance. We are prepared, therefore, to welcome any contribution which may be a real help in improving the health of the worker or combating any condition which may be toxicological or otherwise deleterious. Although there is quite a number of publications dealing with industrial medicine and hygiene, there has been comparatively little published in connexion with the analytical chemistry of industrial poisons. This book attempts to fill this gap and though the treatment of the subject is somewhat uneven, and though there are a good many gaps, it does give something of value in dealing with the particular hazards which are met with in industry.

The preliminary chapters are devoted to sampling procedure and practice, and the methods given for obtaining samples of dust and gases are very good and helpful, as are the methods of dust and gas analysis. In the chapters dealing with the metallic poisons, the methods adopted are clearly set forth, but there is often too much descriptive matter for the skilled chemist, and not enough for the person who is not accustomed to carrying out the particular tests described. One might also question the value of the clinical and physiological information which is given. It is in general correct, but it is insufficient to be of any particular use and it is difficult to ascertain to whom it might appeal.

Industrial solvents and their examination are carefully and adequately described. The author in his colorimetric tests does not appear to use the colorimeter, but depends on using standard colours and matching them by the eye. There is a condensed but useful chapter on the gases of warfare; tables of concentration limits of exposure for fumes, vapours and dusts; the toxicity data of various gases and vapours in the atmosphere, and the limits, inflammability and explosive range of substances likely to be met with in industry.

There is a fairly wide and up-to-date bibliography, mainly referring to publications in the United States, but this is not unexpected as a great deal of the work in industrial toxicology has been carried out in that country.

The index could be greatly improved, and where a number of references are given, some indication should be made as to the more important ones by stressing them in darker type or some other convenient method.

In future editions the author would do well to use the initial or Christian name of the various authors in his references, for without this it is almost impossible to obtain any idea of the authorship of a particular paper, especially if the name is a common one.

Taking it all round, the book is sound, and should be of service to those dealing with industrial medicine and industrial toxicology.

ROGER JOSEPH BOSCOVICH

Roger Boscovich, S.J. (1711-1787)
Forerunner of Modern Physical Theories. By H. V. Gill. Pp. xviii+76. (Dublin: M. H. Gill and Son, Ltd., 1941.) 7*s*. 6*d*.

THOUGH the author speaks (p. 64) of "Newton and other scientists of the time, including Boscovich" as though they were roughly contemporary, this is clearly misleading; for Newton was nearly seventy when Boscovich was born at Dubrovnik (Ragusa) in Dalmatia. This means that one was a man of the seventeenth, the other of the eighteenth century. Similarly, when at the outset of his "Theoria Philosophiae Naturalis", Boscovich asserts that his own system is midway between that of Leibniz and that of Newton, it may be suspected that this is true in the sense that, but for the matter of dates, both would have expressed equal disagreement with his ideas. It is, in fact, hard to understand what he did mean, for the particles of his system never came into mutual contact and they are not subject to the action of a surrounding medium. Yet Boscovich emphatically denied the possibility of action at a distance.

In spite of this inconsistency in his natural philosophy, Boscovich was a voluminous writer who achieved a considerable reputation in his lifetime and even now cannot be dismissed altogether lightly. In order to understand these facts it is necessary to have a clear account of the physical theory which Boscovich developed. But the present small work scarcely touches the history or explains why the theory took the shape it did, or in what way it was founded on the contemplation of experimental facts. In the absence of this background the system seems purely intuitive and to owe its power of adaptation to later problems to good fortune rather than to intrinsic merit.

Indeed the origin of this eighteenth century system seems to have been in the main metaphysical. Its greatest influence was exercised in Great Britain, and particularly in Scotland. In this way it came to the attention of Lord Kelvin, who found a use for it in his later work on elasticity and molecular physics. Similarly J. J. Thomson, when presented with the puzzling properties of his newly discovered electron, had recourse to the ideas of Boscovich. Now again Fr. Gill recalls the Boscovichian corpuscle and sets it to the task of explaining the interference and diffraction of light, the Bohr atom and even wave mechanics in a primitive form. More than this, Boscovich had some clear ideas of the principle of relativity as it involves the perception of scale and orientation. His view of space and time was interesting, though clearly derived to a great extent from the Newtonian theory of fluxions.

The Boscovichian particle is an infinitesimal centre surrounded by a field of force which is alternately an attraction and a repulsion at different close distances, ultimately becoming a positive attraction of the normal gravitational type. Further than this the nature of the particle is undefined, and so it makes a capital plaything for the physicist. But more is wanted to establish a scientific reputation on a sound foundation, and contacts with the past are even more important than contacts with the future.

Hence it may be regretted that here so slight a sketch of the life and character of Boscovich has been included. Yet, if the object was to present a scientific hero, it may have been wise. In truth, Boscovich seems to have been spoilt by success in early life. His character was warped by vanity, egotism and petulance; finally, disappointed with the measure of appreciation which came to him, he became the prey of melancholy and before his death sank into fits of madness. Reverting to the practice of an earlier age, Boscovich wrote a long work, "De Solis et Lunæ Defectibus", a synopsis of astronomy in verse, which Delambre described as uninstructive to an astronomer and unintelligible to anybody else. It is hard without proof to accept the legend of greatness. In some ways Boscovich seems a survival from an age long past rather than a forward-looking man of the eighteenth century. For that century had its really great men, and Boscovich can scarcely be reckoned of their company.

H. C. PLUMMER.

NEWTONIAN ATTRACTION

An Introduction to the Theory of Newtonian Attraction
By A. S. Ramsey. Pp. ix+184. (Cambridge: At the University Press, 1940.) 10*s*. 6*d*. net.

THE preface states that this book was written at the suggestion of some students who were unable to find a book on the subject suitable for their requirements. The seven chapters deal with preliminary mathematics; gravitational attraction and potential, simple applications; attraction and potential internal points, spheres; theorems of Laplace, Poisson and Gauss, general theory; Green's theorem; harmonic functions; attraction of ellipsoids.

In writing an account of a branch of applied mathematics in which the subject-matter has long since been stabilized, an author can still choose his method of presentation, and it is interesting to see that in the first chapter the reader is introduced to vector methods. With the vector notation established, one rather regrets that the matter is not pushed to a conclusion with the introduction of Gauss's general theorem in the symbolic form

$$\int n\,X\,dS = \int \nabla\,X\,dv$$

for the relation between surface and volume integrals. From this form flow the various particular cases of this theorem and Green's theorem. There is the added advantage that the emphasis is thus laid on a statement which is of general application to potential theory whether in gravitation, electricity, magnetism, or hydrodynamics. Indeed, the student of any one of these subjects is seldom forcibly presented with a clear picture showing how much belongs simply to general mathematics and how much to the particular subject which he is studying. Gauss's normal induction theorem and Poisson's equation may be cited as instances.

The book as a whole is intended for students taking an honours course, but the needs of the student reading for a pass degree are not forgotten. The author writes with the clarity and flair for exposition to which readers of his other text-books are accustomed. There are numerous examples at the end of each chapter, many taken from Cambridge and London papers, the easier examples being divided from the more difficult. The book completes the series on mechanics which the author has produced in recent years and takes a worthy place among them.

L. M. MILNE-THOMSON.

A Laboratory Manual of Electricity and Magnetism

By Leonard B. Loeb. Revised edition. Pp. xii+122+112 Experiment Data Sheets. (Stanford University, Calif.: Stanford University Press; London: Oxford University Press, 1941.) 22*s.* 6*d.* net.

THE author raises the old controversy about laboratory work in teaching: Should the student be confronted with a set of apparatus to do an experiment with a title, left with the minimum of prompting to work out the procedure and results to be obtained, and then be given a week or two to write the work up in his own way for subsequent correction by authority, or should he be persuaded to read up previously from specific instructions exactly what he has to do, what theory he is supposed to imbibe for the proper assimilation of the scientific work performed, be given a printed form to fill in with the stated observations and indicated calculations, and so close the deal within a specified laboratory time? Supposing that the latter is the correct procedure, the author could scarcely be bettered in working out a requisite plan. He claims that the hour given to private study, with printed relevant theory (because no course of laboratory work can keep in step with lectures), including pictorial diagrams of connexions (which, we must admit, we had thought had faded out of text-books long ago), before being confronted with the apparatus, leads to a greater efficiency in exercising the student's mind and a more speedy implantment of useful scientific principles. The scheme was developed to avoid the misuse of heredity principles in the recording of experimental work among students.

The experiments in elementary physics are well selected, but they would certainly have been done by scientific students before they reach college in Great Britain. The data sheets, of which several sets are appended, are also impressive. Nevertheless, one feels that the regimentation here presented is a line of least resistance to meet time-table pressure and inadequate laboratory facilities. If it produces the required results, how are these results measured?

L. E. C. H.

Wolf Child and Human Child

The Life History of Kamala, the Wolf Girl. Based on the Diary Account of a Child who was reared by a Wolf and who then lived for Nine Years in the Orphanage of Midnapore in the Province of Bengal. By Dr. Arnold Gesell. Pp. xv+95+8 plates. (London: Methuen and Co., Ltd., 1941.) 6*s.* net.

DR. ARNOLD GESELL has given here a psychological appreciation of the effect on a human child of her transfer in infancy from a human to a lupine family, and of her retransfer after eight or nine years to a human one, based upon the story of an Indian girl recovered in 1920 from wolves. The full story was recorded in a diary kept by the Rev. J. A. L. Singh, under whose care she spent the next nine years, and is to be published by Prof. Zingg of Denver University. Dr. Gesell's account therefore suffers from being based on facts not completely accessible to the reader. In some respects it is hypothetical; we are given a reconstruction of Kamala's unknown infancy and of her eight years with wolves. Some such imaginative reconstruction is probably necessary to the development of Dr. Gesell's theme, which is the interaction of nurture and nature in the formation of culture, and the powers of adaptation, particularly to psychological and cultural environment, of the normal human child, but his approach could have been more strictly scientific and less literary. Any judgment on the facts upon which Dr. Gesell relies would be out of place before the publication of the diary and details which Prof. Zingg is preparing. It will be awaited with no little interest by the readers of Dr. Gesell's book, which will prove, if the facts can be accepted, an important contribution to the study of child psychology and the transmission of culture.

Waves

A Mathematical Account of the Common Types of Wave Motion. By Dr. C. A. Coulson. (University Mathematical Texts.) Pp. xii+156. (Edinburgh and London: Oliver and Boyd, 1941.) 5*s.* net.

THIS book, intended for honours students of mathematics or physics in the final year of their degree course, gives an elementary account of many different types of wave motion. The first chapter contains the fundamental differential equation and its most important types of solution. Chapters ii–v deal with waves in strings, membranes, bars and liquids. Chapter vi is concerned with sound waves, and Chapter vii with electric waves. Finally, Chapter viii returns to general considerations, including the Doppler effect, beats, group velocity, wave packets, Fresnel's principle, and the theory of retarded potential. Each chapter contains a set of important and interesting problems, to which the answers are given. Lack of space is responsible for the omission of elastic waves in continuous media and of radiation from aerials, and some of the work is unduly condensed, in particular the solution of the fundamental equation on p. 7. The book as a whole is very good, and supplies a surprisingly large amount of information in a small compass and at a low price.

Functions of a Complex Variable

With Applications. By E. G. Phillips. (University Mathematical Texts.) Pp. xi+140. (London and Edinburgh: Oliver and Boyd, 1940.) 4*s.* 6*d.* net.

THIS pleasant and moderately priced little book forms an excellent introduction to the complex variable. It is written in a brisk and lucid style, and may be confidently recommended to students of pure or applied mathematics. It will appeal in particular to those who wish to understand the mechanism of conformal transformation. The titles of the five chapters are: functions of a complex variable; conformal representation; some special transformations; complex integral calculus; calculus of residues.

Physics for Engineers

By Sir Ambrose Fleming. Pp. xii+232. (London: George Newnes, Ltd., 1941.) 7*s.* 6*d.* net.

SUCH a wide field can be covered only sketchily in so few pages. Nevertheless, many fundamental principles are outlined and historically traced, with references to sources and proofs. The symbols are not entirely consistent, or in accordance with international standardization, but their meaning is always clear. The value for the student is the historical perspective he can profitably have induced in him and the insistence of the correct derivation of the units he habitually uses.

FEEDING POST-WAR EUROPE

By DR. GEOFFREY BOURNE

University Laboratory of Physiology, Oxford

IN the Atlantic Charter one of the primary post-war objects of the British Empire and the United States is that of freeing the peoples of the world from want. Much has been said and written of plans for post-war reconstruction, and of these that of feeding Europe must be put into operation the moment the War ends, and, unless it is provided for, a situation might well develop which will become completely out of hand.

The problem of feeding Europe after the War is really a dual one. First we must have supplies of the right foods which can be rushed to Europe as soon as hostilities cease. Then, secondly, we must plan for the continued feeding of Europe; and that means planning not only European, but also world agriculture. This latter problem was brilliantly discussed by Sir John Orr at the British Association Conference on Science and World Order last September.

Here it is proposed to deal with the more immediate problem: What foods must the British Empire and the United States hold in readiness to rush to Europe with whatever shipping they can beg, borrow, or happen to have left themselves when the War ends? But before we discuss this matter it is necessary to review the present food position of the various countries of Europe and attempt to predict the direction which food deficiencies will take.

The population of Europe can be divided broadly into two groups of people: the peasant population and the townspeople. The peasants will probably not suffer any serious food deficiency whatever the length of the War. They are the producers, and it is difficult for any nation to ration severely those who produce the food. It is the urban population who will suffer. Not only is food production lowered and imports reduced, in some cases to practically nothing, but in many countries such as Italy, France and Belgium the peasant is withholding grain which might have been sent to feed people in the towns and instead feeding it to pigs and poultry, which sell at considerable profit on the 'black market'. In each country there is also a small well-to-do section which is unaffected by dietary stringencies. These are the people who patronize the black markets, or the hotels and restaurants which do so, or who are able to make up their dietary requirements with the aid of expensive unrationed foods.

Black markets thrive in all the occupied countries, but some are worse than others. Belgium has the biggest black market in Europe. It was so bad that Germany refused to give any help to that country until the Belgian authorities assumed control over all the essential foodstuffs. During 1940 and 1941 huge hoards of black market food were seized from the various restaurants and shops. Even bread is sold on the Belgian black market, and there are reports that potato skins have been sold there too. Black markets closely rivalling that of Belgium exist also in Luxemburg, France and Italy.

Bread is rationed in all the occupied countries and in Germany itself. In some countries where the allowance is generous there is little hardship; for example, Germany 80 oz. a week, Denmark 85 oz., Slovakia 80 oz., Bulgaria 74 oz. In others where it is low, for example, Italy 50 oz. a week, Belgium 55 oz., Greece 30 oz., there may be danger of starvation. (All figures are those for normal consumers.) One may think that 30 oz. of bread is a fairly generous allowance, but such an amount is seriously low when there is so little else to eat. Thirty ounces of bread a week provide about 300 calories a day. The daily requirement of a normal consumer is about 2,800 calories, so that a diet which supplies only 30 oz. of bread a week may be a starvation diet if there is not plenty of other food with which to make up the calories. One way of doing this, in a diet deficient in bread, is by eating a lot of fats or potatoes; but in most countries fats are rationed and in some potatoes also. Belgium has a potato ration of 1 lb. a day, which supplies only 400 calories. Potatoes are not rationed in Greece; but this is of little value because they do not normally form a significant part of the Greek diet. The fat ration is lowest in Finland, where it is 2½ oz. a week; it is very low in Belgium and Italy (3½ oz. a week), and in France (4 oz. a week). The highest fat rations on the continent of Europe are enjoyed by Denmark with 11 oz. a week, and by Germany with 9½ oz. a week.

Meat is officially rationed in all but one country, namely, Denmark. The amount of the ration is not known for all countries, but from the figures available it appears that it is lowest in Belgium (8½ oz. a week) and France (9 oz. a week).

Sugar is rationed in all countries, the lowest being in France, Italy and parts of Hungary (4½ oz. a week).

Besides these standard foods which are rationed, many others, for example, cereal products, cheese, milk, flour, fruit, vegetables, fish, poultry, biscuits, cocoa, chocolate, jam, eggs, etc., are nationally or locally rationed.

In view of the difficulty of satisfying the calorie requirement in France the people have been urged to drink more wine, which has a calorific value of about 350 per pint. This they have done to such good effect that wine has now been rationed. The adult ration is about two litres a week. In Italy most of the population drinks, on an average, half a pint of wine a day and this provides an appreciable proportion of their calorie requirement.

The only countries in Europe to-day in which there is no food rationing are Portugal and Turkey.

Assuming that the average calorie requirement for a non-combatant or normal consumer (that is one not doing heavy manual work) is about 2,800 a day, we can, by examination of the average calorie intake in the various countries of Europe obtain a more accurate estimate of the gravity of the food situation. In the first place, Germany and Denmark have suffered very little so far. The average figure for daily calorie intake in the former is 2,900 and in the latter 3,100. In some of the other countries, however, the figures are not so good. They are the "Protectorate" (Bohemia and Moravia) 2,300, Italy 2,400, Norway 2,500, Occupied France 2,100, Unoccupied France 2,160, Netherlands 2,250, Belgium and Luxemburg 1,870. It is impossible to estimate the calorie intake in Poland and Greece because of the difficulty of obtaining figures for food consumption; but it is almost certain that they are at least as badly off as Belgium. In fact, it seems certain that Greece has been near famine for some months and that the food situation there is now extremely grave. In Poland there is no uniform system of rationing. Germans appear to be unrationed and the Poles receive a better ration than Jews. These figures indicate that many of the peoples of Europe are undergoing slow starvation. It is probable, too, that the figures given represent a rather optimistic estimate of the calorie consumption in Europe.

Deficiency occurs not only in quantity of food but also in quality. There is a serious decrease in the amount of protein eaten, and if this continues, as it is likely to do, it will have a serious effect on the general health of the people of Europe, particularly that of growing children.

There is little doubt that there is a deficiency of certain vitamins. Some months ago Dr. Russell M. Wilder, chairman of the American National Nutrition Council, stated that Germany was starving the peoples of the occupied countries of foods containing vitamin B_1 with the object of lowering their morale. (Adequate vitamin B_1 is claimed to be necessary for the maintenance of morale.) In actual fact it appears that supplies of wheat are so low in Europe that it has been found necessary to extract the grain as far as possible to make the best use of it. Thus most of the wheaten bread eaten in Europe to-day is at least 85 per cent extraction, and is therefore bread comparable with our own National wheatmeal loaf which is relatively rich in vitamin B_1 and most of the other members of the vitamin B complex. We can, therefore, safely assume that of all the vitamins, those of the B group which are found in whole cereals are least likely to be deficient in post-war Europe.

The decrease in the consumption of milk, cheese and butter will result, however, in a reduction of intake of vitamins A and D and of riboflavin. The widespread deficiency of vitamin D may have serious effects, particularly in adolescents who get no priority in food, and who, of all groups in the population, need more of everything. The increase in the use of whole-grain products combined with a restriction of milk will probably cause a widespread calcium deficiency.

In Great Britain an investigation of a series of middle-class diets by E. M. Widdowson and B. K. Alington[1] has shown that the restriction of fruit in the diet has not been compensated for by an increase in the amount of vegetables eaten, and that, therefore, the vitamin C intake has been reduced to half that consumed by the same families in 1935. It is very likely that in Europe there has been a similar decrease in the vitamin C intake of the population, and it is fairly certain that the intake of vitamin C will continue to decrease; but that in most countries it will not reach a level in which there will be serious danger of frank scurvy unless there is a widescale failure of the potato crop. The same principle will apply to Great Britain unless the consumption of vegetables is increased by inspired propaganda. The populations of some countries, such as Norway, Greece and Poland, are probably suffering now from at least a mild form of scurvy and there is every likelihood that this will become worse. Last winter in Norway, even the German army of occupation began to develop scorbutic symptoms, and at the onset of this winter, according to reports, vitamin C tablets were taken to the German army on the Russian front by aeroplane.

It is probable that at the end of this War the following dietary deficiencies will occur to a greater or lesser degree on the continent of Europe.

(1) Absolute lack of food. There will not be enough food to supply the calorie requirements of the populations.

(2) Deficiency of protein, particularly first-class protein.

(3) Deficiency of vitamin D.

(4) Deficiency of vitamin A.

(5) Deficiency of vitamin C.

(6) Deficiency of riboflavin.

(7) Deficiency of calcium.

The difficulty of securing an adequate diet particularly for the 'susceptible classes' (children and pregnant women) is appreciated by the authorities in all European countries. There is a fear in Occupied France of deficiencies, in particular of vitamins A and C, and it is proposed to produce vitamin concentrates from tunny fish liver, carrots, brewer's yeast and lemons to correct these and other possible deficiencies. Children between the ages of six and fifteen are to receive a free distribution of tablets containing vitamins A, C and D. Expectant mothers and children are to receive a portion of a distribution of 160 million vitamin pills which are to cost thirty-five million francs. All European countries are attempting by distributing vitamin pills, or by giving priority in vital foods, to keep their expectant mothers and children in good health. In Luxemburg children get free vitamin A and D capsules. In many Belgian schools the children have been eating a raw carrot every morning, and it is now proposed to distribute to them free milk, chocolate and cod-liver oil. An illuminating sidelight on the Belgian food situation is given by an advertisement which was published last year in a Ghent newspaper, which offered free supplies of vitamins A, C and D to all young men who joined up with a voluntary labour organization. In Germany in the springs of 1940 and 1941 vitamin C tablets were issued to school-children, nursing mothers, infants, soldiers and miners. Heavy workers were included in 1941. In some parts of Germany milk for infants is irradiated to increase its vitamin D content, and from three months onwards babies can receive a vitamin D preparation from the clinics. There seems to have been a possibility of vitamin A deficiency in the German diet, but it was not until January of 1941 that this vitamin was added to margarine.

Having indicated briefly the possible deficiencies which may arise it is now necessary to consider what foods will be required to remedy them. Two foods spring immediately to mind. First, wheat, and secondly, dried milk. Flour of high extraction will supply calories (1,600 per pound, 1,100 per pound when made into bread) and vitamins of the B group. The dried milk may be skimmed or whole. Whole dried milk does not keep as well as the skimmed variety and it would probably be better if the milk were skimmed, and the fat so obtained turned into dehydrated butter which will keep for a much longer time than dried whole milk. The dried skimmed milk will be an excellent source of first-class protein, of sugar, of riboflavin and of calcium. From the dehydrated butter we shall obtain fat (providing 4,200 calories per pound) and the fat-soluble vitamins A and D.

The amount of drying plant and the storage area available are the factors which will limit the amount of dried milk and dehydrated butter which will be available. It will, therefore, be necessary to store extra fats such as whale oil, concentrates of vitamins A and D, and further supplies of protein in the form of dried meat and fish. Some soya bean flour could also be stored with the object of adding it to wheat flour to give an augmented protein and calorie value to bread.

If there is widespread failure of the potato crops in Great Britain and Europe we may be faced with the problem of supplying vitamin C to a large number of people. The plant available for synthesizing vitamin C in Great Britain may be insufficient to supply our own people in such circumstances. The total requirement for vitamin C from all sources for the population of Britain is about thirty tons a year, although it is doubtful if even half this amount is actually consumed. A smaller amount still would be required just to protect the population from frank scurvy. Most of this could probably be obtained from natural sources even if there were no potatoes available, provided equitable distribution of these foods could be obtained. We should be able, however, to offer little help to Europe if there were any serious widespread deficiency of vitamin C there, unless we increased considerably our plant for synthesizing this vitamin. Fortunately, the chances of a pan-European potato failure are not very large, although there may be extensive local shortages. The situation might be met in part by the storage of orange, lemon and grape-fruit concentrates.

In conclusion, we may say that the immediate dietary deficiencies liable to be encountered in post-war Europe can be met if appropriate quantities of wheat, dried skimmed milk, dehydrated butter, whale oil, soya beans, dried meat and fish, vitamin A and D concentrates, synthetic vitamin C and/or citrus fruit concentrates are stored.

It has obviously not been possible in an article of this length to discuss all the ramifications of such a proposal, but at least it has been possible to formulate the problem and to indicate the solution.

POTABLE WATER FROM SEA-WATER

By DR. A. PARKER

Water Pollution Research Laboratory, Watford, Herts.

THE possibilities of obtaining potable water from sea-water by some simple method suitable for use on lifeboats and in similar circumstances have been much discussed during the last few months in the daily Press and in other quarters. Some of the statements made and the opinions expressed have indicated lack of knowledge of the scientific and practical aspects of the problem and of the possibilities and impossibilities. In some instances the statements seem to be of obscure origin and to be reminiscent of the wonderful claims of alchemists of former times. There have been references to a mysterious method of obtaining half a glass of drinking water by adding tablets of undisclosed composition to sea-water. In the circumstances, it seems to be desirable to direct attention to some of the possible methods of removing salt from sea-water to produce potable water, and to indicate their limitations.

Composition of Sea-Water

To understand the problem it is necessary in the first place to know the concentration and nature of the salts in sea-water. Analyses of numerous samples have shown that the composition of the mixture of dissolved salts in the waters of the open sea is practically the same in all parts of the world. Though the composition of sea salt varies little from one sea to another so far as the principal constituents are concerned, there is an appreciable variation in the concentration, apart from the effects of local dilution by inflowing rivers or by melting ice. In general, however, the concentration of the salts in the open sea lies between 32 and 38 parts by weight in 1,000 parts of sea-water, and for the purpose of this article a salinity of 35 parts per 1,000 parts can be taken as an approximate average. An artificial sea-water can be made up by dissolving the following salts in distilled water containing some carbon dioxide and then diluting the solution to give a total volume of 1 litre : sodium chloride, 27·2 gm. ; magnesium chloride, 3·8 gm. ; magnesium sulphate, 1·6 gm. ; calcium sulphate, 1·3 gm. ; potassium sulphate, 0·9 gm. ; calcium carbonate, 0·1 gm. ; magnesium bromide, 0·1 gm. The weights given all refer to anhydrous salts. True sea-water also contains very small quantities of phosphates, silicates, and compounds of nitrogen, and traces of compounds of other elements. The main points, however, are that the concentration of the salts in sea-water is about 35 parts per 1,000 parts, and that nearly 80 per cent of the salt is sodium chloride.

In most of the hard waters used as sources of public water supply in Great Britain, the concentration of the salts in solution is not more than about one hundredth of the concentration of the salts in sea-water ; the salts in hard water are mainly the bicarbonates and sulphates of calcium and magnesium which are easily removed by chemical precipitation, whereas sodium chloride cannot readily be removed completely by simple chemical precipitation. It is thus clear that the problem of removal of salt from sea-water is much more difficult than that of softening ordinary hard water. At the same time, it should be mentioned that it is not necessary to remove the whole of the salt from sea-water to produce potable water. Most people would consider that water containing not more than 0·8 part by weight of sodium chloride in 1,000 parts is not too unpleasant for drinking ; but to reduce the salinity of sea-water to this value means removing more than 97 per cent of the salt. In some circumstances it may be satisfactory to drink water containing as much as say 4 parts of salt in 1,000 parts, but to reduce the salinity of sea-water only to this value would require the removal of nearly 90 per cent of the salt.

Treatment

Distillation. An obvious method of obtaining drinking water from sea-water and one which has long been used in certain parts of the world for considerable quantities of water is to boil the sea-water and to cool and condense the steam evolved. With evaporators or stills able to produce 5–20 tons of distilled water a day from sea-water, and of simple design and without elaborate equipment to conserve heat, there is no difficulty in obtaining 6–7 tons of distilled water for each ton of coal or oil burnt. If the equipment is designed and operated greatly to reduce the losses of heat by radiation and convection from the evaporator and condenser, and to recover heat from the steam, 9–10 tons of distilled water and even more can be obtained for each ton of fuel consumed. To obtain this greater efficiency requires more elaborate and costly equipment and more skilled supervision.

The question at once arises as to whether it is practicable to design a small still, which can easily be operated and will utilize the fuel with reasonable efficiency to produce say 1 pint of distilled water an hour. If the still is of simple design so that it is unlikely to fail under difficult conditions, it is improbable that the high efficiencies of some large installations can be obtained. With careful attention to the design of the still and the burner, it may be practicable in some circumstances to obtain five or six volumes of distilled water from sea-water with the combustion of one volume of oil or spirit; this represents an efficiency of heating and evaporation of the order of only 50 per cent. The space occupied by the equipment and fuel, and the weight in relation to the quantity of distilled water produced, are important factors. Investigations are in progress on the possibilities of designing a still and burner suitable for use in lifeboats. It must be emphasized, however, that the conditions to be met are stringent and the difficulties to be overcome are great. There must be no appreciable risk of failure in any part of the still or the burner.

Absorption of Water Vapour. It is possible to obtain drinking water from sea-water by utilizing the property possessed by certain substances such as silica gel of absorbing large quantities of water vapour. If silica gel is exposed over the surface of sea-water, the gel absorbs water vapour from the moist air; this vapour is replaced in the air by the natural evaporation of the sea-water, and the process continues until the absorptive capacity of the silica gel is exhausted. If the gel has been suitably prepared it may take up water vapour equal to about one fifth of its own weight. This absorbed water can be removed by heating the gel, and the vapour so obtained can be condensed by cooling. After heating, the gel can be re-used and the process repeated. In effect, this method is similar to that of simple distillation but is less efficient and presents greater difficulties.

Freezing. It has long been known that drinkable water can be obtained by melting the ice formed on cooling sea-water. As the cooling proceeds, ice separates until the remaining liquid is saturated with the salts; the solid which afterwards forms is a mixture of ice and salt. Though the latent heat of ice is very much less than the latent heat of evaporation of water, it is unlikely with present methods of refrigeration that a simple apparatus could be devised to produce drinking water from sea-water so efficiently as by distillation.

Hydrates. Another possible method is to add to the sea-water salts which dissolve readily when the water is warm and which on cooling the solution separate as crystals containing a considerable proportion of water of crystallization. The crystals can be removed and, on heating, some of these hydrated salts lose water of crystallization as vapour which can be condensed. The remaining de-hydrated or partially de-hydrated salt can then be re-used. Substances other than salts also form hydrates. A method of this kind could not be carried out so simply and efficiently as distillation.

Osmosis and Electro-osmosis. If sea-water is placed in the middle cell of a vessel divided into three compartments by two semi-permeable membranes, and fresh water is placed in the outer compartments, salts slowly diffuse from the middle compartment into the water in the outer compartments. In this way the salinity of the sea-water is decreased.

To bring about any great reduction in the salinity, very large volumes of fresh water must be circulated through the outer compartments. The quantity of fresh water required can be reduced considerably by placing electrodes in the outer compartments and passing current between them so that positive ions such as sodium migrate to one side and negative ions such as chlorine migrate to the other side. Even with this system, which requires a large expenditure of electricity, the quantity of fresh water which must be circulated through the outer cells is much greater than the quantity of sea-water converted into drinking water. This method thus seems to be impracticable.

Chemical Precipitation. It is possible to remove practically the whole of the magnesium, calcium, chloride, sulphate, bromide and bicarbonate from sea-water by the addition of chemical reagents which react with these radicals to form insoluble compounds. For example, addition of lime water precipitates magnesium as hydroxide, and bicarbonate as calcium carbonate; and soluble salts of silver remove chloride and bromide as insoluble silver chloride and silver bromide. There is much more difficulty in removing sodium and potassium, as the simple salts of these metals are all to some extent soluble. Several complex salts of sodium, which are sparingly soluble in water, are the basis of recognized methods of quantitative analysis for sodium. The conditions of precipitation, however, have to be carefully controlled, and some of the best of the precipitating agents are toxic.

Even after precipitation of the various radicals as insoluble substances, the complete separation of the precipitates is not easy, as some of the precipitates are in a finely divided condition and are not readily removed by filtration. Any toxic substances must also be removed if the treated water is to be satisfactory for human consumption. It thus seems that it is not easy to devise a simple method of removal of salts from sea-water by chemical precipitation.

Base-exchange and Acid-exchange. It has been known for a long time that certain aluminosilicates possess base-exchange properties and can remove calcium and magnesium from water. The process has been in use for some years in the well-known household water softeners and on a much larger scale in softening water for public supply and for industrial purposes. The sodium compound of the aluminosilicates is ordinarily employed for this process of water softening. When the hard water is passed through a bed of granules of the sodium compound, the calcium and magnesium bicarbonates and sulphates in the water are replaced by the soluble sodium salts, and the sodium in the aluminosilicate is replaced by calcium and magnesium. When the whole of the replaceable sodium has entered the water and has been replaced by calcium and magnesium, the material is regenerated for further use by treatment with a solution of sodium chloride, whereby the calcium and magnesium are again replaced by sodium. Though the process softens water, it does not reduce the total quantity of salts in solution.

In 1934, during the course of experiments at the Chemical Research Laboratory, Teddington, for the Water Pollution Research Board of the Department of Scientific and Industrial Research, B. A. Adams and E. L. Holmes[1] discovered that certain synthetic resins possess base-exchange properties. These resins have the advantage over the aluminosilicates that they are insoluble in dilute solutions of acids, such as sulphuric and hydrochloric acids. It was also discovered that other resins with acid-exchange properties can be prepared. By treating saline water with a base-exchange resin, previously regenerated with a solution of sulphuric acid or hydrochloric acid, the sodium chloride in solution is replaced by hydrochloric acid. When this water is treated with an acid-exchange resin, previously regenerated with a solution of an alkali, the hydrochloric acid is removed. In this way the whole of the salts can be removed from the water.

At about the time of the discovery of the exchange resins, several investigators in different parts of the world found that base-exchange material similar in properties to the base-exchange resins can be prepared by treatment of coal with strong sulphuric acid. This material can also be used in conjunction with acid-exchange resins to remove dissolved salts from water. The acid-exchange resins are unique in that no other substances have been discovered with similar acid-exchange properties.

Base-exchange materials and acid-exchange resins are now in use in several parts of the world for the removal of salts from certain waters, not nearly so saline as sea-water, to produce the equivalent of distilled water, and for the recovery of valuable materials from trade waste waters.

In sea-water the concentration of the salts in solution is so great that the volume of the exchange materials required to remove the salts is about the same as the volume of potable water obtained. It may be, however, that investigation will lead to some improvement, though the prospect of considerable improvement within a short time is not great.

It is also possible that further investigation will lead to some practicable method in which the salts are removed partly by exchange materials and partly by chemical precipitating agents. The difficulty is to develop a method which is simple in operation.

Conclusion

It may be that investigations now being made will lead to some practicable method, suitable for use in lifeboats, of obtaining drinking-water from sea-water by simple distillation or by the use of base-exchange and acid-exchange materials and chemical precipitating agents. Any method proposed, however, must be submitted to stringent tests before it is recommended, if undue risk of failure with serious consequences is to be avoided.

Meanwhile arrangements have been made to provide lifeboats with larger quantities of drinking-water than has previously been the practice.

THE ANTHROPOLOGICAL APPROACH TO THE STUDY OF MUSIC

By F. H. ANGOLD

In attempting any study of this kind, or seeking to gain some light on the question of the relationship between anthropology and music, it is necessary to define the term music. The dictionary does this in the following terms: "Melody or harmony; any succession of sound so modulated as to please the ear; the science of harmonic sounds, or the art of producing such; rhythmic order."

With this definition in mind we have to realize that the definition was an attempt to explain something already in existence: musical performance preceded the definition of meaning. Music is therefore an attribute of man, apparently as old as man himself. In style to-day it varies as widely as do the characters of the human species. It is not confined to any one particular aspect of man's existence: he gives vent to music on occasions clouded by sorrow, equally as on others which are brightened by seasons of joy. We are led therefore to ask: Why on all occasions does man turn to music as the medium for the expression of feelings which words might prove inadequate to define? The animal is able to give vent to sound, the bird to trill its notes of music; man alone possesses the power to define the gifts with which he is endowed. The music used by man to express his joy or sorrow does not necessarily come exclusively from man himself; he co-operates with Nature. This reminds us of Beethoven who, visiting in after years the place where he composed his fifth and sixth symphonies, remarked to his friend Schindler: "Here I composed the 'Scene by the Brook' and the yellowhammers up there, the quails, nightingales and cuckoos round about, composed with me"[1].

To-day, music like painting is a specialized art: in earlier times it was the gift of all men. There is evidence that Palæolithic man had his music and at least possessed a primitive type of flute made with reindeer horn, while relics of the Bronze Age reveal prehistoric horns made of metal[2].

In modern civilized society the musician, like the painter, performs a particular task; he fulfils the normal functions of man, functions which so far as the majority are concerned have become atrophied through non-use. This development in the history of man has had a diverse effect upon his well-being. It means that while the vast majority may be unable to express their feelings in musical terms, the person devoting himself entirely to musical composition has been able to create a type of music far removed from the crude melodies of more primitive people. This, however, is not the whole story, for we find that the Sumerians and the Egyptians had developed a high standard of musical instruments. A good idea of the type of instruments in use may be gained from the works of Canon F. W. Galpin, Sir Leonard Woolley and C. Engel. We are faced therefore with a musical knowledge of great antiquity[3].

The question arises as to whether harmony was a feature of this ancient music, for in China there is melody but not harmony. We find that the Greeks used a crude accompaniment of drone bass to some of their songs, while Pythagoras about 600 B.C. introduced intervals. The five-toned pentatonic scale is the most primitive form now in use among civilized people. This was the form chiefly used by the Chinese even four thousand years ago, and is used in such familiar hymns as "There is a Happy Land," and Scottish songs such as "Ye Banks and Braes"[4]. That this pentatonic scale is of great antiquity in Asia there can be little doubt ; it is also interesting to find that the scale in music of Scottish and other Celtic races bears resemblance to the pentatonic scale of the ancient North American Indians[5].

In his book "Science and Music" Sir James Jeans suggests a possible manner by which organs originally designed for registering pressure in water became adapted for registering the pressure of the air, thus becoming associated with sounds and the presence of food and danger[6]. He suggests that as the result of a period of drought the fishes came on dry land (according to the geologists about 300 million years ago), the survivors eventually becoming pure land animals, and incidentally our ancestors. The new functional operation was a gradual development from the old. The illustrations in Jeans's book which are a photographic record of eddies caused by sound and water are full of interest. One shows an eddy formed at the lip of a flute organ pipe, another depicts the eddies formed by drawing an obstacle through still water, while yet another shows the type of eddy formed in water as it streams past a long thin wire. Looking at these photographs I was at once reminded of some of the Chinese landscape paintings 山水 where the water eddies are frequently depicted in a manner almost identical with the illustrations given by Jeans. Such eddies may be seen in the painting "Ten Thousand Li down the River", by Hsia Kuei, a reproduction of which is to be seen in "Chinese Art", by Ashton and Gray[7]. Incidentally, these eddies closely resemble the 'running spiral', a design which figures prominently in ornamental decoration all over the world. It seems probable that science is revealing to the present age things which in remote times were familiar but have long been obscured to the more sophisticated. If, as Jeans suggests, we are the descendants of water creatures which became pure land animals, involving a change in the functional use of our organs, we may have an explanation for the similarity in sound and water eddies. Maybe the Chinese with their greater measure of placidity have been able to keep in mind what we have lost.

The Chinese writer, Lin Yutang, describes music in the following terms : "Music is pure sentiment itself, dispensing entirely with the language of words with which alone the intellect can operate. Music can portray for us the sounds of cowbells and fish-markets and the battlefield ; it can portray for us even the delicacy of flowers, the undulating motion of the waves, or the sweet serenity of the moonlight ; but the moment it steps outside the limit of the senses and tries to portray for us a philosophic idea, it must be considered decadent and the product of a decadent world."[8]

The question of sound is full of interest. Drums and rattles seem to have been the earliest types of musical instruments ; they still figure prominently in the world of music. The hour-glass-shaped drum of China was in use in the Indus Valley early in the third millennium B.C.[9]. It has been suggested that the drum came into being as a means for reproducing the sounds made by the footsteps of walking man[10]. We are all familiar with the use of the drum for military purposes, and the part it plays in keeping men in step on the march.

Music is therefore based on hearing, the modern composer is an individual who possesses the ability of hearing sounds which to the less sensitive ears are non-existent, and of being able to put those sounds on record. Man must have music ; the closer man lives to Nature the more musical his life becomes. In music man unites with the other members of creation and, dispensing with words, using a medium common to all creatures, gives vent to sound and in so doing seeks to harmonize with Nature. He becomes a part of that undying flame, of which all through the ages man has been aware but never able to explain—life. We find therefore that modern man is not far removed from his more primitive ancestors. We may listen to some of the crude music of the African, or the weird chants of the Indian ; they are expressive. Then we may turn our thoughts to tunes such as "All through the Night", the Welsh tune without words, but one which admirably expresses the night coming over the mountains. As we listen the scene comes up before us. Or take another example, the Irish tune "Londonderry Air", to which there are no proper words. It conjures up a picture of Ireland, soul-stirring to the depths. To-day we are divided into groups. Not only is the composer in a class apart, but the ordinary people are also divided into sections : on one hand, those who are able to appreciate and enjoy music, and on the other, those who are less fortunate. Even these sections are subdivided, for among the music lovers we have those whose interest lies mainly in classical music, while others find complete satisfaction in jazz. In seeking to understand such diversity we are confronted with the fact that it is not always the educated class who appreciate good music, thus introducing the vexatious question of the difference between culture and education. We are also made aware of another fact.

Music, being creative, is therefore of necessity peaceful ; warlike music in consequence is anomalous. Music, like painting, transcends the barriers of nationality and race ; in consequence it serves as signposts to the path of man's ultimate salvation. The fact that under modern conditions it is the particular interest of the few may help to throw some light upon the tragedy of modern times, and any increasing interest shown by the majority must serve to indicate that man is slowly coming to realize what he has lost. A greater interest can only tend to reveal the truth that man's interests are common the world over, and any attempt to study the relationship of man to music must help to lead men back to the fundamental truth that there is but one race—the race of men.

OBITUARIES

Prof. James Wilson

The first professor to be appointed to the chair of agriculture in the Royal College of Science for Ireland by the Department of Agriculture and Technical Instruction for Ireland was James Wilson, a Scotsman who, as a student and a young agriculturist, had already won distinction in his native country, and whose death occurred on December 9, 1941. It is now forty years since he delivered his first set of lectures to Irish students, who for a period of twenty years received from him successive courses in technical agriculture and to whom the memory of Wilson will ever remain dear.

He very quickly gained knowledge of Irish conditions and made a special study of the economics of agriculture in the country. Numerous papers on this subject appeared in the *Journal* of the Department of Agriculture and elsewhere. As a result, Wilson's influence soon extended beyond the sphere of the lecture room and in a short time he became a leading figure in the field of Irish agriculture. Naturally, a man of his talent found himself in conflict with certain aspects of agricultural practice, and, consequently, much of his writing was of a controversial nature. He thought independently and wrote forcibly, but his pleasing style and frank exposition won the admiration of his readers, while his erudition commanded the respect even of those with whom he disagreed.

Wilson's greatest contribution was, however, in the sphere of scientific agriculture. He was an ardent student and an untiring worker, and his many publications on the breeding and feeding of farm stock testify to his industry and ability. Most of his scientific work is recorded in the *Scientific Proceedings of the Royal Dublin Society*, in the activities of which he took the keenest interest. He specialized in Mendelian heredity. Among his productions on this and cognate subjects are the following books: "A Manual of Mendelism", "The Principles of Stock Breeding", "The Evolution of British Cattle". Later his attention was directed to stock feeding, on which subject numerous contributions flowed from his pen. The comprehensive volume, "The Principles of Stock Feeding", was his latest big work in this connexion.

As a lecturer and teacher Wilson endeared himself to his students. His geniality was overflowing and his method of imparting knowledge quite fascinating. Formal lectures he disliked: he preferred to converse with his class and a feature of his lecture was that the students talked as much as the professor. His students are now engaged in a variety of agricultural activities where the influence of the teacher will be manifest for many a year.

J. P. Drew.

Mr. Geoffrey Milne

The death, at Nairobi on January 16, of Mr. Geoffrey Milne, of the East African Research Station, Amani, at the age of forty-three, deprives the world of a most able and experienced investigator of tropical soils. Mr. Milne, who was the brother of Prof. E. A. Milne, Rouse Ball professor of mathematics in the University of Oxford, graduated at the University of Leeds in 1921, to which he returned after a period as agricultural chemist in the University of Aberdeen, to occupy a post in the Department of Agriculture. He joined the staff at Amani in 1928 and quickly earned a reputation in the field of soil geography. It is largely due to his efforts that soil cartography has been unified throughout the East African dependencies and a rational basis established for soil classification. He combined in an unusual degree the qualifications of a geographer and a laboratory worker, and of a theoretical and a practical soil scientist.

Mr. Milne will be remembered chiefly as the editor and principal compiler of the first soil map of East Africa, published in 1936. The map, though necessarily incomplete, introduced many novel features of soil cartography. In particular Milne made use for the first time of the concept of the 'catena', a sequence of several soil types recurring in regular order in association with certain types of topography, usually undulating or hummocky. This marked the formal recognition by soil cartographers that the delineation of type of landscape may be equally important on a soil map as type of soil.

In recent years Milne was much occupied by the urgent practical problems of soil conservation in East Africa, and in 1938 made an extensive tour of the American soil-conservation stations. Afterwards he published a report of his tour that gave an exceptionally vivid picture of the state and organization of soil research work in the United States. At the time of his death, he was about to take up the post of scientific secretary to the East African Supplies Board.

Prof. F. von Müller

Prof. Friedrich von Müller, emeritus professor of internal medicine at Munich, a brief announcement of whose death appeared in the *Schweizerische medizinische Wochenschrift* of November 29, was born on September 17, 1858, the son of the director of the Augsburg Hospital. After studying medicine at Würzburg and Munich, where he qualified in 1882, he became assistant to Prof. Carl Gerhardt, whom he accompanied to Berlin in 1885. He was afterwards appointed professor of medicine at Marburg, Basle and finally at Munich, where he became director of the Second Medical Clinic.

According to Garrison, who describes him as "perhaps the most scientific teacher of internal medicine to-day", he had one of the most largely attended clinics in Europe. He was well known in Great Britain, where he was elected an honorary member of the Clinical Section of the Royal Society of Medicine in 1933. His first publications were devoted to problems of physiological chemistry, such as the metabolism of albumin, fat absorption, the origin of urobilin, and metabolism in fever and convalescence. Later he directed his attention to various departments of internal medicine, including intestinal intoxication, exophthalmic goitre, Bright's disease and bronchitis. His principal books were a handbook of clinical diagnosis in collaboration with O. Seifert (1886), investigations on two fasting men (1893) and some problems in metabolism and nutrition (1900).

J. D. Rolleston.

We regret to announce the following deaths:

Prof. T. Levi-Civita, For. Mem. R.S., formerly professor of mechanics in the University of Rome, on December 29, aged sixty-eight.

Prof. Virgilio Tedeschi, professor of biological physics in the National University of La Plata.

NEWS and VIEWS

Royal Meteorological Society: New President

The election of Prof. D. Brunt as president of the Royal Meteorological Society will be welcomed by all meteorologists. Prof Brunt received a mathematical training at Cambridge and lectured on mathematics before joining the Meteorological Section of the Royal Engineers in 1916. During the War of 1914–18 his first book appeared, on "The Combination of Observations", which gave a systematic account of the application of mathematics to observational data, especially in meteorology; it reached a second edition in 1931. After the war ended, he joined the staff of the Meteorological Office as superintendent of Army Meteorological Services, where he remained until 1934. During this period he carried out a great deal of research into periodicity in meteorological phenomena, bringing to the subject rigid mathematical criteria of reality which did a great deal to correct the rather credulous attitude of earlier workers, and disposed of the belief in dominant 'weather cycles'. He then turned his attention to dynamical meteorology and to the fundamental physical properties of the atmosphere, especially in connexion with radiation. In 1934 he was appointed to the chair of meteorology at the Imperial College of Science and Technology, succeeding Sir Gilbert Walker. In the same year he published his well-known text-book on "Physical and Dynamical Meteorology", from which most of the younger generation of meteorologists have received a thorough grounding. He was elected to the fellowship of the Royal Society in 1939. Prof. Brunt has been associated with the Royal Meteorological Society for many years, as councillor, vice-president, editor and as the author of numerous stimulating papers in the Society's *Quarterly Journal*.

Conference on European Agriculture

The British Association announces a conference on "European Agriculture: Scientific Problems in Post-War Reconstruction", arranged under the auspices of the Division for the Social and International Relations of Science as a matter arising out of the recent conference on Science and World Order. This agricultural conference will be held on Friday and Saturday, March 13 and 14, in the rooms of the Royal Society, Burlington House, London, W.1. There will be morning and afternoon sessions on each day, and British and foreign experts will deal with such subjects as the immediate technical steps necessary for reconstruction, settlement, marketing and prices, farm and factory, nutrition, the co-operative system, land reforms, peasant prosperity, excess population, peasant education, the improvement of peasant farming, livestock problems, artificial insemination, milk production, market gardening, and the relations of European agriculture to world conditions. A regional survey of European agriculture is contemplated, inasmuch as it is felt that many of the problems of reconstruction may be better viewed regionally than within the limits of political divisions. The chair of the opening and closing sessions will be taken by Sir John Russell; the names of other chairmen and of speakers will be announced when the programme is complete. Further particulars can be obtained from the Secretary, British Association, Burlington House, London, W.1.

Science and World Order

A bulletin has been issued by the British Association summarizing action taken and inquiries made by the officers and council of the Association and the executive of the Division for the Social and International Relations of Science, down to the end of January, on matters arising out of the Conference on Science and World Order. *The Advancement of Science*, No. 5 (Pp. 120, 5*s*.), contains a full report of the transactions of the Conference, together with certain related communications received later. A Penguin volume on "Science and World Order", based on the proceedings of the Conference and compiled by J. G. Crowther, D. P. Riley, and Dr. O. J. R. Howarth, is in preparation. On the direction of the Council of the Association, the executive subcommittee of the Division convened a meeting, which included representatives of Government and other bodies interested in building and territorial planning to consider what action, if any, might be desirable on the part of the Association in connexion with this matter. It was decided to form a representative committee, in accordance with a regular practice of the Association, to inquire into and report upon the state of science in relation to building and territorial planning, with the view of summarizing the present position of researches in these connexions and indicating their services.

The executive subcommittee of the Division, on the instruction of the Council, held a meeting, with assessors, to consider what action, if any, should be taken by the Association in relation to post-war university education. It was decided that a committee be appointed with wide terms of reference, as follows: (*a*) To consider the general policy and methods of university education with a view to promoting international collaboration and the free interchange of ideas, and relating university education to the needs and service of the community; (*b*) to consider the replanning of teaching departments and curricula in accordance with modern conceptions of the inter-relations of different branches of knowledge, particularly those of science and the humanities; (*c*) to survey the position regarding teaching material, apparatus, books and staff in universities which have been damaged, destroyed, disorganized, or closed as a result of the War, and to make recommendations for their rehabilitation. This committee is in progress of formation; its joint secretaries are Prof. F. E. Weiss and Mr. A. Gray Jones.

Certain further matters have appeared, after inquiry, not to call for action, or at any rate immediate action, on the part of the Association. Thus, the Council has taken no immediate action upon various suggestions, made during and after the Conference, concerning the establishment of an international league of science, and a standing consultative committee representative of British and foreign science in Great Britain. The Council endorsed the view of the executive subcommittee of the Division that the International Council of Scientific Unions and the Unions themselves, if effectively reconstituted after the War, should provide adequate opportunities for international co-operation in science; and it is understood that discussions to this end are in progress. The Association received a report arising out of proposals for a register of, and meeting-place for, foreign men of science now in Great Britain. It is understood that material exists for a register in the records of the International Labour Department of the Ministry of Labour and of other organizations; also that another organization is contemplating the provision of facilities which may offer arrangements for periodical meetings of allied scientific workers.

Carrots for Domestic Animals

WAR conditions have established the merits of carrots as an ingredient of the human dietary: that they are no less excellent as a food for farm animals, is shown in a recent article by Mr. H. E. Woodman, of the School of Agriculture, Cambridge (*J. Min. Agric.*, 48, No. 3, 185; 1941). Indeed, all kinds of stock are fond of carrots, and although their importance in animal feeding is overshadowed by that of the other root crops—swedes, mangolds and turnips—this is not due to any inferiority in feeding quality, but rather to price considerations and to the fact that when the human requirements in Great Britain have been met, the supply of carrots left over for animals has usually been quite small. This year it seems there will be a large surplus. On the basis of starch equivalents, 80 lb. of carrots should be able, on an average, to replace 100 lb. of mangolds, or 90 lb. of swedes. With the more watery turnips, however, two parts by weight may be replaced by one part of carrots. Carrots are not so rich as swedes in vitamin C, the anti-scurvy factor, but are distinguished from all other roots by their high content of carotene. Since this yellow pigment is convertible into vitamin A in the body of the animal, it follows that carrots are a good source of this important health factor.

Raw carrots have always been a favourite food for horses. The allowance should not exceed 20 lb. per head per day, but smaller amounts may be fed with benefit to condition. They should be used in partial replacement of oats, 7 lb. of carrots being equal to 1 lb. of the cereal. Dairy cows may receive up to 40 lb. of sliced carrots per head per day and fattening bullocks up to 60 lb. The carotene in the carrots enriches the colour of winter milk and improves its content of vitamin A, and for this reason, carrots are specially valuable when the dairy ration contains neither kale nor silage. They may be used to replace dried sugar-beet pulp (7 lb. of carrots = 1 lb. of dried beet pulp) or cereals (8 lb. of carrots = 1 lb. of crushed barley). Pigs may also be given carrots with advantage to health and condition; and cereal meal, up to one fifth of the total ration, may be replaced by this succulent food, of which 8 lb. should be fed for every lb. of cereal meal replaced. The carrots form a useful source of vitamin A for pigs that are kept entirely indoors. Some authorities recommend cooking or steaming them for pigs, but the full beneficial effect is only obtained when they are fed raw. Grated or shredded carrots, when mixed with the meal ration, provide a palatable and health-promoting feed. Carrots form a useful supplement to the growing and laying mashes of poultry during winter, and their vitamin A potency is particularly beneficial in these cases. They are best fed raw. Grated or shredded carrots may replace cereals up to one fifth of the total mash, 8 parts by weight being used to replace 1 part of cereal.

Carnegie Corporation of New York

IN the report of the president of the Carnegie Corporation of New York, covering the year ended September 30, 1941, Mr. Frederick P. Keppel, who retired from the presidency on November 18, states that of grants totalling 2,706,834 dollars made during the year, 500,000 dollars were allocated for matters relating directly to the national emergency. Special stress is laid upon the importance of timing in enterprises involving effective co-operation between public and private agencies, public offices, and private citizens or groups. Besides contributions to the National Academy of Sciences totalling 100,000 dollars, emergency grants were made to the Institute of Public Administration for special studies undertaken at the request of Government agencies, to Harvard University for training supply officers, to the National Bureau of Economic Research and the Institute of Pacific Relations, as well as to other agencies. Of other grants, 398,511 dollars was allotted for library interests, including support of the *Journal of Documentary Reproduction*, 566,930 dollars for adult education and 906,956 dollars for research and studies. The Committee on Scientific Aids to Learning has steadily proceeded with its work in the fields selected for intensive study, namely, the problems of microphotography, including visual fatigue, and the development of the best visual and auditory equipment for classroom use. From the special fund set aside by Mr. Carnegie for the Dominions and Colonies, 70,000 dollars was allotted for library and educational services in Trinidad and the Windward and Leeward Islands, 30,000 dollars for the research activities of the International Labour Office at McGill University, 14,800 dollars to the Canadian Research Council in the Social Services and 7,500 dollars to the Royal Institute of International Affairs for a study of the internal economy and external relations of Newfoundland; a further grant has also been made to the Carnegie Endowment for International Peace.

Mr. Keppel's report includes a review of developments and changes in the field of activity of the Carnegie Corporation during his nineteen years of office, in which he emphasizes the possibility of a foundation adjusting itself to meet sharply changing conditions if its house is in order financially and otherwise. Its trustees should not only represent financial judgment and experience but also lay opinion, and they should possess a true understanding of the importance of education in a civilized society. He also stresses the value of a closely knit programme in each field of activity, and the necessity of being prepared to withdraw from a field in which the law of diminishing returns begins to operate, and finally the importance of timing, of endeavouring to have the idea, the man and the setting in perfect conjunction: the idea, vital and timely; the scholar or executive at the peak of his powers; and the organization at flood tide.

Rodent Pests in War-time

MR. A. D. MIDDLETON has given some useful information for the control of the rabbit population of Great Britain (*J. Min. Agric.*, 48, No. 2). He believes the best prospects for success depend upon better co-ordination of effort with county pest officers instead of individual efforts at control without co-operative schemes, but that it is unreasonable to commercialize it and to expect a profit from rabbit control. However, the high price of rabbits and the intensive efforts of gamekeepers and trappers appear to have reduced the rabbit to comparative scarcity over most parts of Great Britain, a position approaching that of the end of the War of 1914–18, when wild rabbits became very scarce. On the other hand, the position of the rat is still serious, and in some 'blitzed' centres and ports with bigger food stores than usual, conditions have encouraged its increase. In an article on rat control (*Lancet*, 1, No. 5, 1942), Mr. Eric Hardy directs attention to the value of asbestos and three-ply wood as rat-proofing materials when many usual materials are unobtainable. White arsenic is the most useful of the poisons permitted by the law. Attention is also directed to the need for using more traps—even ten times as many traps as rats—and to using unbaited traps, and the encouragement of those predatory enemies of rats in the countryside usually destroyed by game-preservation, namely, stoats, foxes, badgers, owls, herons, otters, buzzards and polecats. The Ministry of Food's Infestation Order 1941, which came into force in January, gives added power for compulsory control of rats and other warehouse vermin.

/ood Pigeon Investigation

THE British Trust for Ornithology is organizing a winter wood pigeon investigation in the British Isles which ought to shed much light upon the habits of this serious agricultural pest. Although organized from the natural history point of view, the investigation may well provide information of considerable value in the control of this pest. Explanatory forms and recording cards for field counts and roost positions have been circulated, and the inquiry will also include the examination of crop-contents of shot birds and post-mortems upon diseased birds. The field counts will make observation upon the sizes of the local flocks at every opportunity when they perch, feed, roost or are in flight, and in addition to recording the day and place, the hour of the count will be noted. Record will also be made of their daily feeding, drinking and resting times, and the influence, if any, of fog, mist, rain and increasing daylight, and if special fields are favoured for feeding and resting. Observations will be made to see if the flocks remain intact throughout the day or break up, and if pairing takes place in flocks. The roost observations will count or estimate the number of birds using the roosts, the type of wood, the trees most favoured, the period in use, and whether it is used annually and if the size of the roosting flock is increasing or decreasing. An effort will also be made to get experienced people to weigh, measure and determine the sex of shot wood pigeons. The field counts will be returned to the Edward Grey Institute at Oxford monthly, and the rest of the winter stage of the investigation will be completed by the end of May.

The Swedish Botanical Garden

THE January issue of the *Anglo-Swedish Review* announces that the Bergianska Trädgården or Bergianum, the botanical garden of Stockholm, is to mark its hundred and fiftieth anniversary this year. It was founded in 1791 by Peter Jonas Berg, a doctor of medicine and a botanist, who bequeathed it to the Swedish Academy of Science. It consists of a purely scientific botanical section and a practical section, which in peace-time carries on a large exchange of seeds with most of the botanical gardens abroad. Among the latter is the botanical garden of Tokyo, which had to place considerable orders to complete its collections, part of which were destroyed in the earthquake ten years ago. The Bergianum is also in close touch with the United States, and some plants from the salt steppes of Russian Turkestan recently came from Russian botanical gardens. Most of the seeds received are of purely scientific interest, but sometimes seeds and plants of commercial value are also received. The results of experiments on the effects of the vigorous cold of the last two years on different plants will shortly be published in *Acta Horti Bergiani*, which contains the results of research work in systematics, cytology and embryology. The celebrated collection known as "Iconotheca Botanica Bergiana" contains 10,000 photographs by most of the botanists in the world. A large room in the main building is filled with cupboards which originally belonged to Bergius and contain his collections of plants and insects. Thanks to a donation, the Bergianum will soon have a winter garden where all the flora of the Mediterranean will be grown.

Public Health in India

ACCORDING to the annual report for 1940 of the Public Health Commissioner with the Government of India, there were no abnormal outbreaks of disease in that year, and the common epidemic diseases such as malaria, smallpox and plague had been less prevalent than in 1939. The most important public health event was the third meeting of the Advisory Board of Health at Poona, where reports were made on the compulsory inoculation of pilgrims at festival centres against cholera and on the control of food adulteration. The Board recommended a plan for the provision of laboratories, including for each Province or State a central laboratory, regional laboratories for groups of districts and others for individual districts. The low incidence or complete absence of the common infectious diseases such as cholera, smallpox and plague in the prisons, of which the daily population was more than 13,000, showed the efficacious control of these infections. The report also contained a chapter on medical research, especially on nutrition, by the Indian Research Fund Association, field studies on cholera, plague and malaria, leprosy research carried out mainly at the Calcutta School of Tropical Medicine, and maternal mortality investigated at Calcutta, Bombay, Delhi and Madras. Cerebrospinal fever had occurred in sporadic form in many provinces.

Radio Receiver Design

IN the past few years radio manufacturers in Great Britain have awakened to the fact that the export industry has been very much neglected. This is shown clearly in a paper read before the Students and Graduates Sections of the Institution of Electrical Engineers by Mr. J. H. Lemmon, on "Tropical Receiver Design" (*Quart. J. Inst. Elec. Eng.* of December 1941). In British colonies, the majority of radio receivers in use until about 1938 were of either American or Dutch origin. British manufacturers had sent out to India or other tropical countries receivers which differed very little from those sold in the home market, and little attention was paid to the internal parts of the receiver. Mr. Lemmon takes India as the basic country, since a fairly comprehensive knowledge of the radio markets there is available. In India, where the transmitters may be many hundreds of miles apart, medium-wave broadcasts are not of very much use, except for local listening-in areas near the large towns. They cater mainly for the local inhabitants and native listeners, and the value of the programme transmitted from one town may be of very little use in an adjacent area. The European listener abroad wants to hear programmes and news from his home country, and for this reason he has to rely on short-wave listening. The most used wave-lengths for this purpose are in the 13-, 16- and 19-metre bands, which give reliable services over very long distances for the greater part of the year, while certain other stations work on 30-, 60- and 90-metre bands. The exported radio receiver therefore, in addition to withstanding tropical conditions, should cover all wave-bands from 13 metres to 90 metres, and also medium waves between 200 metres and 330 metres.

Infra-Red Radiation in Industry

A PAPER on "Infra-Red Radiation and Equipment: their Application to Industrial Processes", read recently by Mr. R. Maxted before the Illuminating Engineering Society, emphasizes that the technique of radiant heating depends on direct experiment rather than upon an understanding of wave-length effects, properties of materials, etc., although a knowledge of the spectral characteristics of the materials is necessary if optimum combinations of wave-bands and materials are desired. Transformation into sensible heat is one effect of the absorption of radiant energy, and radiant heating depends entirely upon this effect, the energy absorbed by the material being instantly converted into heat upon exposure to radiation. The incident energy is partially reflected, transmitted and absorbed when any substance is irradiated, the magnitude of each effect ranging throughout the electromagnetic spectrum with any given material. The direct effect of absorption is that energy is re-radiated at longer wave-lengths, change of structural state takes place, or sensible heat is produced within the absorbing substance.

Radiant heating is usually employed for dehydration, enamel stoving, or other change-of-state phenomena, and it is believed that the practical results obtained are solely due to heat application and not to any structural change arising from the direct action of radiation. Further developments may conceivably lead to the utilization of spectral effects but present-day practice aims at applying heat. It should be noted, however, that while interest centres in the thermal effects of absorption, the material receiving heat treatment is not necessarily the absorbing substance; an enamelled metal sheet, for example, may be irradiated from the back, or a transparent lacquer may be indirectly heated by absorption in the under surface.

Summer School in Human Biology

DURING the last year, the Educational Advisory Board of the British Social Hygiene Council has arranged, in co-operation with local education authorities in different parts of the country, refresher courses in biology for teachers. These were primarily designed to help to equip teachers with a background of biological knowledge, to undertake, in the schools, courses similar to the School Leaver's Courses proposed by the Board. In several areas teachers attending these lectures have expressed a wish for a further course of practical work, and to meet this demand, and that of other teachers, a summer school in human biology has been arranged to be held in Cambridge during August 5–19.

The school is planned to be of help to teachers in junior and senior schools and the junior forms of secondary schools. Each morning there will be a lecture on some biological topic, followed by practical laboratory work. The practical work will consist mainly of fairly simple experiments and demonstrations of such a nature as to be of use in schools where comparatively little equipment is available. In the afternoons there will be organized excursions to places of interest such as various research laboratories and biological museums and institutes. After tea each day there will be seminars at which practical teaching problems will be discussed, and there will be a display of biological films and text-books.

Most evenings after dinner will be devoted to lectures, by eminent biologists, on the social implications of biology. Accommodation will be provided in one of the colleges for both men and women. There will be free time in which the members of the school will be able to visit the colleges and other places of architectural and natural interest. Further details may be obtained from the Education Officer, British Social Hygiene Council, Tavistock House South, Tavistock Square, W.C.1.

Food and Nutritional Needs

THE Nutrition Society has arranged a whole-day conference on "Food Production and Distribution in Relation to Nutritional Needs" to be held on February 28, beginning at 10.30 a.m., at the London School of Hygiene and Tropical Medicine. Papers will be read by Sir John Orr ("The Agricultural Implications of a Food Policy Based on Nutritional Needs"), Dr. N. C. Wright ("Rival Claims of Animals and Man for Food"), Mr. E. T. Halnan ("Animals as Food Converters") and Sir John Russell ("Planning for Agricultural Production"). Among those who have agreed to participate in the discussion are Prof. A. W. Ashby, Sir Joseph Barcroft, Mr. A. N. Duckham, Prof. H. D. Kay and Dr. T. F. Macrae. Sir Wilson Jameson (chief medical officer, Ministry of Health) will take the chair at the morning session. Provisional arrangements have been made for further meetings to discuss, among other topics, (1) "The Preparation of Food in War-time with Special Reference to Collective Feeding" and (2) "Nutritional Requirements for Optimum Health". Further information about the Nutrition Society can be obtained from the Hon. Secretary, Dr. Leslie J. Harris, Dunn Nutritional Laboratory, Milton Road, Cambridge.

The Newton Tercentenary

NEWTON was born on Christmas Day, 1642. The Physical Society will celebrate the tercentenary of his birth by holding a special meeting at which an address will be delivered dealing with the life, work and influence of Newton. The lecturer will be Prof. E. N. da C. Andrade, Quain professor of physics in the University of London. Details of the meeting will be announced later.

LETTERS TO THE EDITORS

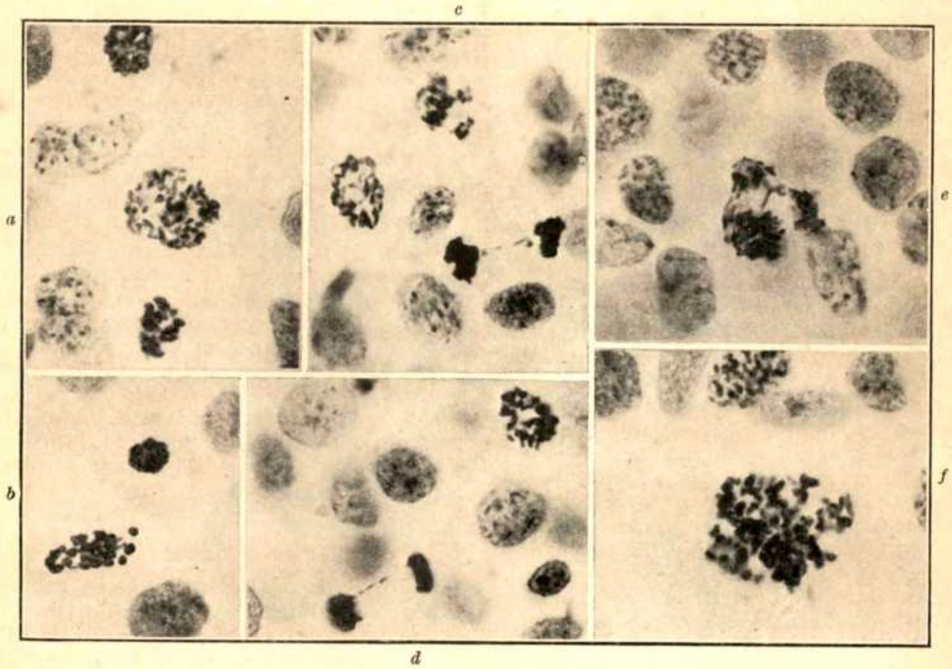
The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

A New Technique for Mitosis in Tumours

In cancer therapy it is of great interest to distinguish between tumours according to their degree of mitotic activity. This requires a determination of he proportion of dividing to resting cells. It may ven be useful to follow the character of mitosis after X-ray treatment. Human cells are difficult to andle for this purpose. The usual techniques are edious and unsatisfactory. Indeed, misleading conlusions have often been reached owing to the indequacy of the preparations used. In contrast with he older methods, I find that La Cour's aceticacmoid (resorcin-blue) treatment[1] is rapid and, as may e seen from the photographs, capable of showing oth the character as well as the stage of division.

The method is as follows. Fix small pieces of umour in acetic-alcohol (1 : 3) for 10 min.–24 hr. efore staining, cut small shreds of tissue from the urface with scalpel and transfer them into 10 per ent acetic acid for five minutes and 45 per cent for en minutes. Then stain with warm (40° C.) aceticacmoid for 15–30 minutes. Put one drop of aceticacmoid on slide with one piece of stained tissue. rush the tissue by tapping with the blunt end of a one needle-holder. Remove all unmacerated fragents. Cover and press with blotting paper to spread he cells and remove surplus stain. Heat slide gently ithout boiling. It is at once ready for study. If equired for further use, keep slide 1–5 days in moist atmosphere at freezing point and make it permanent by the usual method[1]. In order to make well-stained permanent preparations, leave tissue in aceticlacmoid for twenty-four hours. Using the above method, good smear preparations of rat carcinoma and mouse sarcoma have also been obtained.

Fixed tumour tissues can be stored in 70 per cent alcohol, but the best preparations are obtained from freshly fixed material. If the tissue is left in fixative more than forty-eight hours the chromosomes swell and their staining is not satisfactory.



Microphotographs showing various types of dividing cells in tumour of the cervix. Magnification 2,300. (Material was kindly supplied by the Radium Institute, Manchester.)

(*a*) Two diploid and one tetraploid mitotic metaphase.
(*b*) Abnormal mitotic metaphase in a haploid cell; only 24 chromosomes are present.
(*c*) Delayed separation of two daughter chromosomes at anaphase.
(*d*) Chromatid bridge at mitotic telophase.
(*e*) Tripolar spindle in a tetraploid cell.
(*f*) Highly polyploid, probably octoploid cell in division.

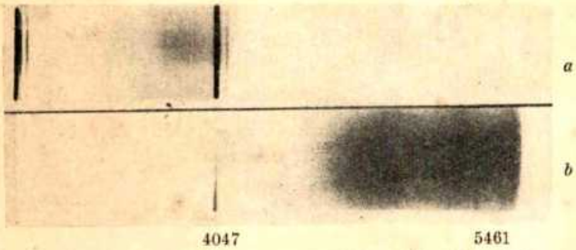
Fluorescent Lipoidal Spectra of Human Tissue

Hieger[1] pointed out that most of the carcinogenic hydrocarbons studied were highly fluorescent and they produced characteristic bands in the regions 4,000, 4,180 and 4,400 A. The investigation of the presence or absence of similar spectrographic characteristics in non-malignant and malignant tissues was instituted with the end in view that it might shed some light on the presence of possible carcinogens in the latter.

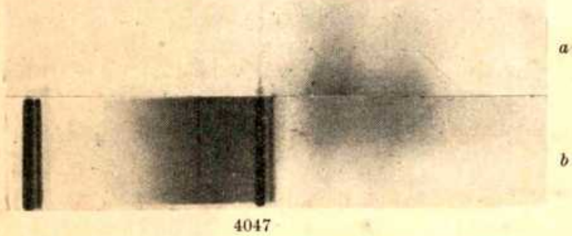
In 1935 I suggested the possibility that "cholesterol or some of its decomposition products" may, under certain conditions, act as carcinogens[2]. Among such compounds methyl cholanthrene is considered "the most active cancer-producing agent known . . . yet the actual presence of any such substances in traumatized tissues has not been demonstrated"[3]. On the basis of the hypothesis of cholesterol carcinogenesis this work dealt primarily with an acetone-soluble lipoid fraction obtained from human cancer tissue.

In connexion with the fluorescence phenomenon it was noted that the cancer tissue lipoids produced a far stronger fluorescence within a given period of time than the lipoids obtained from non-malignant tissue.

The apparatus used consisted of a spectrograph, made by combining a direct-vision spectroscope, in which the spectrum, produced by a glass prism, was photographed with an $f/2 \cdot 5$ camera, a mercury arc, and a filter eliminating light up to about 3,400 A.



FLUORESCENCE OF (*a*) NON-CANCEROUS; (*b*) CANCEROUS TISSUE, PARTIALLY DEPROTEINIZED.



FLUORESCENCE OF (*a*) METHYL CHOLANTHRENE; (*b*) CANCEROUS TISSUE, MAXIMUM DEPROTEINIZATION.

A Pyrex container specially blown to egg-shell thickness, of about 50 mm. in diameter and about 40–50 mm. in depth, was placed with the solution directly under the filter. The spectrograph was placed at right angles to, and about 10 mm. from, the container. It is noteworthy that an empty Pyrex container did not register any fluorescence above 4,047 A.

All tissues used were carcinomata. Briefly, the lipo-proteins were prepared as follows:

Tissue was minced, then ground very finely with sand and extracted alternately with acetone, petroleum ether, and acetone, 250 c.c. of solvent to 100 gm. of tissue. These extracts were pooled, evaporated and then treated with excess acetone to precipitate out the lecithins. The acetone solution was then placed in a refrigerator for forty-eight hours, filtered and evaporated. (This may have to be repeated until residue gives a clear solution in excess cold acetone.)

Other methods, whereby a greater amount of lipo-protein may be obtained from a given quantity of tissue, are being investigated. The results will be published in a subsequent communication.

About 10 c.c. of the lipo-protein was shaken vigorously with 3–4 times its volume of a saturated alcoholic solution of mercuric chloride and allowed to stand about twenty-four hours. To this was added a saturated alcoholic solution of caustic potash until pH8 or higher was reached. This was filtered. and the precipitate washed several times with petroleum ether, which was added to the filtrate. The partitioned petroleum ether fraction was then pipetted off, washed again with alcohol caustic potash solution, re-pipetted off, evaporated and the pale yellow lipoid fraction taken up in CP toluene. The resultant solution (about 0·5 per cent) must be clear.

The spectrographic differences between partial and maximum deproteinization as well as the difference between normal and malignant fractions are shown in the accompanying plates. These differences are easily recognized.

There seems to be a qualitative as well as a quantitative difference in the fluorescence between non-cancerous and cancerous tissue lipoids. Spectrographic characteristics identical with those found in methyl cholanthrene are evident in the lipoid of human cancer tissue (carcinoma).

I wish to express my sincere thanks to Prof. Joseph Kaplan and to Dr. S. M. Rubens of the University of California at Los Angeles, for their co-operation and assistance in obtaining the spectrographic data in connexion with this work.

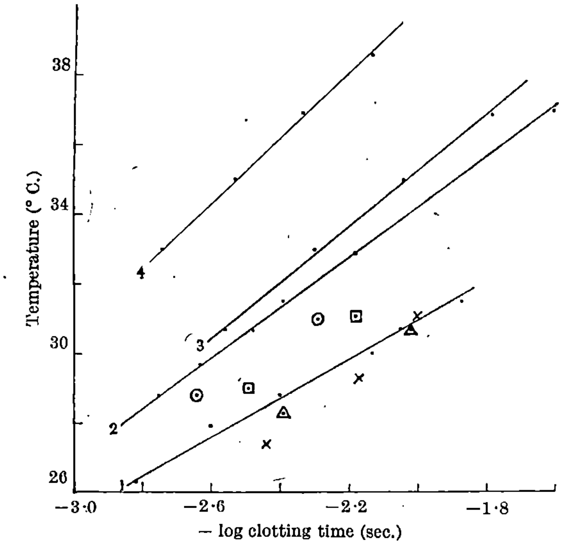
The Second Phase of Rennet Coagulation

Various hypotheses have been put forward in attempts to explain the clotting of milk by rennet. That from the Carlsberg Laboratories[1,2] has probably been the most widely accepted. This theory states that the clot is due to the precipitation of the insoluble calcium salt of paracasein after the enzymic alteration of a constituent of the original casein, which is presumed to behave, before this alteration, as a protective colloid for the other constituents. Thus the coagulation process can be divided into two phases, one enzymic and one non-enzymic. It has been generally agreed that these two phases can be differentiated, but their precise nature has not yet been made clear.

This note is concerned with the second phase sometimes referred to as the precipitation of calcium paracaseinate[1,3]. This is probably not the simple precipitation of an insoluble salt; for example, it does not occur readily at a low temperature. Effront states[4] that below 15° C. milk is not clotted by rennet although the enzyme does alter the protein. Most chemical changes, including the majority of enzyme reactions, have a temperature coefficient of 2–4 per 10° C. That this coefficient holds approximately for rennet over the range 37°–0° C. is shown by the fact that the first phase is completed at 0° C. after a definite time which can be calculated from that required at 37° C. For example, a sample of milk which contained sufficient rennet to clot it in eight minutes at 37° C. was kept at 0° C. for 130 minutes ($130 = 8 \times 2 \cdot 12^n$, where $n = 37/10$). Its clotting time at 37° C. was then 90 seconds. Longer storage at 0° C. caused only a slight further reduction of clotting time. This took place at the rate of seconds only per day. Thus a method is available for separating the two phases of rennet action, and the effect of various factors, such as temperature on the second stage, can be studied.



1. Raw milk, No. 1
2. Raw milk, No. 2
3. Pasteurized milk
4. Reconstituted spray-dried skim milk powder

⊙ No. 2 after 24 hr. at 0° C.
▷ No. 2 after 48 hr. at 0° C.
⊡ No. 2+N/5,000 $CaCl_2$ after 24 hr. at 0° C.
× No. 2+N/500 $CaCl_2$ after 24 hr. at 0° C.

Using samples of milk on which rennet has been allowed to complete the first stage of its action at 0° C., it has been found that the relation between temperature and rate of clotting over a range of clotting times from 1 to 9 minutes is described by the equation

$$R_{(T+t)} = R_T e^{kt},$$

where $R_{(T+t)}$ is rate of clotting at $T+t$° C. (1/clotting time in seconds), R_T is rate of clotting at T° C., and k is a constant, the value of which depends upon the milk.

Thus the graph obtained by plotting log rate against the temperature is a straight line. The observed values of k were 0·46 for fresh milk, 0·32 for another milk which had been preserved at 1° C. for a day, 0·28 for pasteurized milk, and 0·25 for reconstituted spray-dried skim milk. These values of k correspond to temperature coefficients $\left(\frac{R_T+1}{R_T} = e^k\right)$ between 1·6 and 1·3 per degree. The only relevant reaction with a temperature coefficient of this order is the denaturation of proteins. That of ovalbumin has a coefficient of 1·9 per degree between 60° and 70° C., while the corresponding figure for hæmoglobin is 1·3 over the same range[5]. It is therefore suggested that the second phase of the coagulation of milk by rennet is a denaturation (unfolding and relinking of polypeptide chains) or partial denaturation of the casein, which has been rendered heat-sensitive by the enzyme.

This hypothesis is supported by the sensitiveness of the reaction to calcium ions. Addition of calcium equivalent to N/5,000 in the milk led to a decrease in clotting time of 18 per cent, and an increase to N/500 caused a decrease of 61 per cent in the clotting time. The temperature coefficient of the reaction was not affected by the presence of added calcium.

A phosphorus-containing protein from malt wort also exhibits this phenomenon[6]. In the absence of calcium, it can be heated under certain conditions for several hours at 100° C. without coagulating, but in the presence of N/200 calcium chloride it coagulates as soon as the temperature reaches 50° C.

Most of the lines in the accompanying graph converge as the temperature diminishes and would meet between 10° and 20° C. if the relation still held. This would mean that the differences between the milk samples used affected the temperature coefficient only, and that therefore, for example, the contents of calcium ion were equal. The fact that a very small quantity of calcium exerts such a large effect suggests that the quantity of ionized calcium originally present is very small.

It is thought that the observations recorded here will provide a means by which many factors controlling milk coagulation may be studied, and that the hypothesis put forward may be of use in such investigations.

Lowland Tropical Podsols in Uganda

RICHARDS has stated[1] that there are indications, though no definite evidence, that lowland tropical podsols are found in Africa. Such soils appear to exist in one small area of Uganda, near Lake Nabugabo, which is adjacent to the north western corner of Lake Victoria (lat. 0° 20′ S., long. 30° 50′ E.). These soils, which are just above the level of Lake Victoria (altitude 1,135 m.), are derived from recent lake deposits of sand. The deposits are poor in bases, like the sands of tropical Asia and tropical America from which podsols have been formed: the poverty in bases is reflected in the composition of the water in Lake Nabugabo, where the alkaline reserve varies between 0·00027 and 0·00029 normal, as compared with the average figure 0·0012 for Lake Victoria[2].

Analyses of the Nabugabo soils are not available and cannot be undertaken at the present time, but there seems no doubt that they must be regarded as podsols; they are very acid in reaction; the surface layers are dark with organic matter and there is a layer of bleached sand in the subsoil. In the hollows well-marked peaty deposits have developed.

Some of the plants in the peaty hollows at Nabugabo have been recorded from other swamps; for example, the tall grass *Miscanthidium violaceum* Robyns, which is common there, is dominant in many swamps in the west of Uganda. Several species, however, have been found in no other locality in the Protectorate. The most notable is *Sphagnum macromolluscum* Dixon, dominant over an area of some acres at Nabugabo but not known to occur anywhere else. Other species of Sphagnum are common on some of the mountains, but there is no record of them at altitudes below 3,000 m., with the exception of *Sphagnum Franeonii* Warnst[3].

Many species of Utricularia also are found at Nabugabo, among them being *Utricularia appendiculata* Bruce, *U. erecta* Kam., *U. exilis* Oliv., *U. exoleta* R. Br., *U. Kirkii* Stapf, *U. obtusa* Sw., *U. prehensilis* E. Mey., *U. reflexa* Oliv., *U. spiralis* Smith, *U. stellaris* L., *U. subulata* L., *U. Thonningii* Schumach. The genus Utricularia does not seem to be so well represented at any other place in the Protectorate, although some of these species have been found at much higher altitudes on the mountains.

Trichopteryx gracillima C. E. Hubbard is another species recorded from the peat logs of Nabugabo but from no other locality in Uganda. *Drosera Burkeana* Planch. also has been found nowhere else in Uganda, but *D. madagascarensis* D. C., which is more abundant at Nabugabo, is also more widely spread.

The type specimens of several of the species enumerated above have been collected in recent years at Nabugabo and, therefore, it seems probable that similar deposits of peat at low altitudes are not very common in tropical Africa. No other striking examples of lowland podsols have been noticed in Uganda, nor is it to be expected that they would occur: for nowhere else at low altitudes is there the same combination of a climate with a heavy rainfall and of soils made up of leached sands. Eggeling[3] has suggested that at low altitudes in Uganda the Sphagnum community develops only where the natural succession is upset and cites other examples where it has occurred in annually burnt Miscanthidium swamps.

Miscanthidium violaceum is dominant in many swamps in the west of Uganda, and scattered plants of Sphagnum, Utricularia and Drosera are often found in association with it. The soil reaction in these swamps is always very acid but the subsoils, when tested by the chemical section of this department with Comber's reagent, have given a bright red colour, showing that the iron had not yet been leached out.

Crocodiles, which are abundant in Lake Victoria, are absent from Lake Nabugabo. The reason has remained a complete mystery. Lake Nabugabo was formed when a sand spit shut off a bay of Lake Victoria, and at the present time it is separated from the larger lake by a stretch of level ground, only three quarters of a mile wide, which could easily be crossed by crocodiles. Yet no crocodiles have been seen in Lake Nabugabo, although the temperature of the water and the supply of fish would seem to be favourable to them.

It is possible that the water of the lake which, near the eastern shore beside Lake Victoria, has a faint peaty smell and is acid in reaction, may be so distasteful to crocodiles that they avoid it. If this is the case, it is an interesting example of the complexity of the ecosystem, in that the character of the soil has controlled the distribution of so large an animal as the crocodile.

Value of Molybdenum for Lettuce

IN the course of work on the minor element constituents of Chilean nitrate, the value of molybdenum in improving the growth and health of lettuces has been apparent. With one part of molybdenum (as sodium molybdate) in ten million parts of nutrient solution the plants are larger, deeper green and appear to be much more resistant to disease. This improvement occurs whether the molybdenum is used alone or in conjunction with one or more other minor elements as strontium, titanium, vanadium, chromium and zinc. Preliminary experiments even suggest that molybdenum can fend off symptoms of boron deficiency for some time in the early stages of growth, but this point needs confirmation.

If molybdenum in such small doses can definitely be shown to render lettuces less susceptible to disease, it may prove to be a valuable asset to commercial growers, whose losses from various causes are very considerable.

Sociological Research in Race Relations

IN the light of some present sociological research in the subject of race relations in Great Britain, may I be allowed briefly to endorse the general arguments advanced by Mrs. Neville-Rolfe in her article on "Biology as a Social Science"[1], and more particularly her paragraph on social biology in education?

So far as my present observations show, popular information in respect to problems of human heredity and human biology in general has barely advanced out of the stage of superstition in many aspects, and much confusion exists over the meaning of various terms of technical or semi-technical usage. Perhaps the most common confusion is in respect to the connotation of the word 'race'. This term is used and accepted quite freely as a synonym for 'nation', 'people', or any other similar concept for which an alternative noun cannot readily be found. There appears to be also a fairly wide and quite unanalysed acceptance of such conceptions as 'national psychology', etc., the logical implications of which are that an individual's cultural or social behaviour is 'inherited' much in the same manner as the colour of his skin. Further mysticisms surround the biological and social implications of the phenomenon of racial miscegenation, and that 'blood' itself fulfils the function less romantically ascribed to the genes is as usual an explanation of heredity as the existence of 'criminal types' and the 'science of bumps'!

The 'etiology' of this core of popular 'knowledge' need not be discussed here. The situation, however, plainly suggests that there has been something seriously amiss in previous educational policy. The moral would appear equally plain. Without a foundation of up-to-date information on such subjects it is not easy to see how the average citizen can face with any clarity the many complex problems that are involved in modern social and political policy.

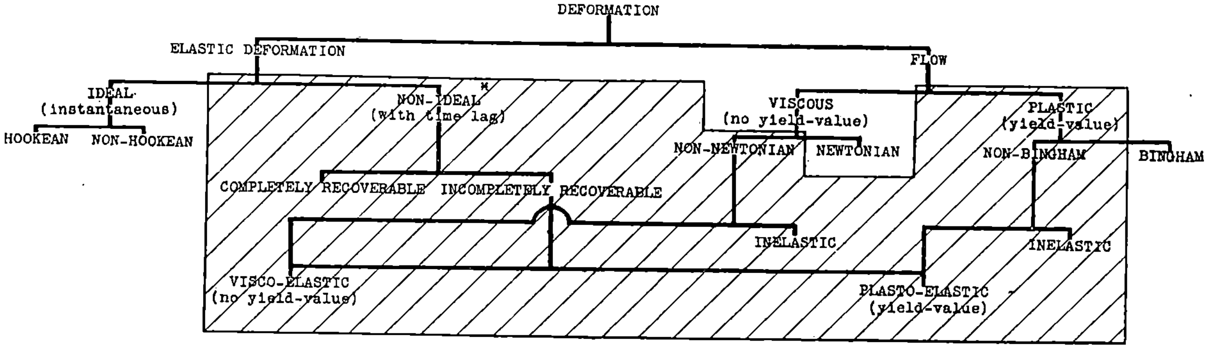
CLASSIFICATION OF RHEOLOGICAL PROPERTIES

THROUGH the courtesy of Prof. M. L. Oliphant, the British Rheologists' Club held a meeting at the Physics Department, University of Birmingham, on Saturday, January 24. After business proceedings, a discussion on "Classification of Rheological Properties" was introduced by Dr. L. R. G. Treloar, on behalf of the committee of the Club.

Dr. Treloar reminded members that at the annual general meeting of the Club, the question of definitions had been discussed and the committee had been instructed to draw up a tentative scheme for classification of properties of materials subjected to specific conditions, rather than to define terms many of which might not even approximate to the behaviour of real materials. This scheme, which was to be regarded as preliminary and subject to modification, is shown on the accompanying table.



WORKING DEFINITIONS

Elastic Deformation—recoverable deformation.

Flow—non-recoverable deformation.

When flow starts only above a critical stress (**Yield-Value**) it is **Plastic**. When flow starts at all stresses, however small, it is **Viscous**.

Hookean—obeys Hooke's law, stress proportional to strain.

Newtonian—obeys Newton's law, stress proportional to rate of shear.

Bingham—obeys Bingham's law, rate of shear proportional to stress less yield-value.

An elastic deformation is **Ideal** when the whole of it follows immediately on the application of a stress. When it does not, it is classed as **Non-Ideal**.

Note. Categories within the hatched area are liable to change of rate of deformation under constant stress, the rate either increasing or decreasing.

* In the case of a spring and dash-pot in parallel, the system could obey Hooke's law if the stress were applied sufficiently slowly but not if it were applied fast. In some other systems a direct proportionality between stress and strain is not obtained however slowly the stress is applied.

Deformations are conveniently subdivided into elastic deformations and flow, the former being generally defined as 'recoverable' and the latter as 'non-recoverable'. Recoverable deformations are subdivided into those which are 'ideal', in which a definite strain occurs immediately on the application of a stress, and those which are non-ideal, showing a time lag. Ideal deformations may be Hookean (that is, directly proportional to stress) or non-Hookean. By definition, ideal deformations are completely recoverable, but non-ideal deformations may be either completely or incompletely recoverable. The latter give rise to visco-elastic deformations corresponding to systems which show no yield-value, that is, the smallest applied stresses produce a deformation.

Flow may be viscous (no yield-value) or plastic (yield-value). Here Dr. Treloar stressed the fact that postulating such categories does not imply that it is believed that real materials follow these definitions *exactly*. We need not suppose that any material shows a *perfect* yield-value; still less that there are any perfect Bingham systems in Nature (that is, systems which flow at a rate strictly proportional to the excess of the applied pressure over the yield-value). These categories are of use in giving a practical approximation to the behaviour of real materials.

Deformations which are produced only after a yield-value has been exceeded but which do not obey Bingham's law may be subdivided into inelastic and plasto-elastic; the latter differs from visco-elastic only in showing a yield-value.

Returning to viscous systems which show no yield-value, these may show Newtonian (rate of deformation proportional to stress) or non-Newtonian flow. The latter group subdivides into inelastic and visco-elastic, thus re-merging with the elastic group.

The table should also be extended in another dimension to allow for the fact that, for example, under constant stress, the rate of deformation of many materials accelerates (thixotropy, false body, etc.) or decelerates (work-hardening, dilatancy). Detailed subdivision of these properties has not yet been attempted by the committee but, so that the importance of such properties should not be forgotten, all categories for which such behaviour is not precluded by definition are included in a hatched 'frame'.

Dr. Treloar concluded by expressing the hope that members would criticize this table freely both with respect to suggested alterations and additions.

Dr. G. W. Scott Blair, honorary secretary of the Club, said that he thought members ought to know how much the committee owed to Dr. Treloar for his contribution to the preparation of the table. He had only one other point to make, namely, that those who worked in specialized fields would doubtless find the table still inadequate in the special parts which concerned them. For the present, a number of phenomena which are known to exist have been omitted since they are not of great practical importance, and it is hoped for the present to keep the table simple. Thus, just as rate of deformation can increase or decrease at constant stress, so the partial differential of strain with respect to stress can likewise increase or decrease with stress considered at any given time. This would necessitate a second frame and a further subdivision of the 'non-ideal' category, but the committee believes that this is best not included for the present.

Mr. van Someren suggested that it would be helpful if each category could be considered in turn, and suggestions offered by members (not for inclusion in the table) of materials which would, under specified conditions, approximate in their behaviour to the category in question. This was done, though in some cases the suggestions were tentative.

There was some discussion on the meaning of 'recoverable' as applied to deformations. Dr. Scott Blair pointed out that the committee meant by 'recoverable' that the energy causing the recovery must be part of that originally applied and stored potentially, whether the recovery is spontaneous or initiated by some outside agent such as heat, mechanical or supersonic vibration, etc. Some members felt that 'recoverable' should be subdivided into 'spontaneously recoverable' and 'recoverable by activation by some external agent'. No final decision was reached and the committee was asked to consider the matter further.

A member raised the question of 'seepage' when the composition of a material is altered as it is deformed, and Mr. J. C. Gage pressed the point that many complex properties such as thixotropy, false body, dilatancy, etc., have not yet been dealt with in the classification. Dr. Scott Blair said that the committee was grateful for such comments and would bear them in mind, and Dr. V. G. W. Harrison asked that members should express freely any views they might hold, especially about any important omissions in the table.

Mr. van Someren pointed out that, at the top of the table, elastic deformations appear on the left and flow ('liquid') properties on the right; whereas at the bottom, the plasto-elastic deformations, implying yield-values, a property of solids, are now on the right, and the visco-elastic on the left. The committee might consider some slight modification of the table by which this apparent anomaly might be avoided.

Mr. Maunder Foster stressed the importance of the adhesive properties of many materials, and gave some account of the significance of this group of rheological properties in the boot and shoe industry.

Dr. T. L. Ibbs, who had presided during the meeting, concluded by saying that, as a non-rheologist, he appreciated the simplicity of the table. It was easily understood by those who were not highly specialized in rheology, and he, for one, hoped that this simplicity might be maintained.

Following the discussion, it was unanimously resolved to accept the table of classification as a basis for further discussion.

Dr. G. W. Scott Blair then read a paper on "Rheological Developments Past and Present", illustrated by lantern slides. A number of members also showed apparatus and materials of rheological interest.

G. W. Scott Blair.

INVESTIGATIONS ON LIGHTNING IN NIGERIA

In a recent paper entitled "The Measurement of Lightning Voltages and Currents in Nigeria, Part 2, 1938–1939", read in London before the Institution of Electrical Engineers, F. R. Perry, G. H. Webster and P. W. Baguley record the details of an investigation on the magnitude of lightning voltages and currents on Nigerian high-tension transmission lines, and continue an earlier work commenced by one of the authors. Three-phase oscillographic and klydonographic records of voltages were obtained, together with magnetic link measurements of currents on pole and lattice-mast structures. In addition, continuous records have been obtained of the interchange of current between earth and atmosphere during weather disturbances. The investigation resulted in a large amount of data for statistical analysis, and the results derived are briefly summarized below.

Surges of all types were analysed and resulted in wide variety of wave shapes, having wave-front values varying from 0·2 to 65 microsec., and wave-tail values from 0·9 to 93 microsec., the lowest values being generally associated with flash-over conditions. In general, the ratio between the length of wave tail to length of wave front covered a limited range of 1·2/1 to 4/1, higher values being obtained on occasions, these ratios being practically independent of the wave front and tail magnitudes. These values were, for example, smaller than for the 1/50 microsec. wave usually adopted as the test standard.

A number of records of direct stroke voltages were also obtained, most of these being associated with power system faults caused by line insulation flash-over. In such instances, the complete sequence of events was not always apparent, but it has been found that the recording of voltages on all three conductors is preferable to single-phase recording, a more complete history of the phenomenon being obtained. In two cases, it was found possible to obtain wave-shape records of the constituent strokes of multiple-stroke flashes, resulting in evidence of the family resemblance of such strokes. Certain aspects of the oscillographic records of lightning voltages were confirmed by klydonograms, the data obtained from the latter, however, being less accurate, and, in general, not so complete.

Current measurements were made in the case of direct line strokes, the line in this instance being supported by tubular steel poles, and in addition, the current distribution in the members of a lattice structure was obtained; of these, one set of such measurements involving eighteen lattice masts still awaits analysis.

Pronounced double pulses were obtained in certain oscillographic records of lightning voltages, and the suggestion is made that these are dependent on the current pulses in the main return lightning stroke, as was the opinion of Malan and Collens. Many of the observations made at Kew have been confirmed by observations made by means of a point-discharge recorder, certain differences relating to storm activity being simultaneously revealed with a contrast between temperate and tropical zone storm conditions. It was apparent from these records that a more complicated form of a Simpson-Robinson storm model could advantageously be applied to the task of explaining point-discharge records of lightning phenomena.

Following upon an analysis and discussion of the data obtained, certain suggestions are made as to the lines upon which future investigation should be conducted, and it is suggested that a study should be made of the voltages produced by multiple-stroke flashes to transmission lines, and an attempt made to ascertain whether any relationship exists between voltage pulses and the predicted currents fluctuating in lightning return strokes. It is further suggested that these data could be got most efficaciously by combining photographic studies obtained by a Boys camera with simultaneous oscillographic records of the corresponding lightning surge voltages. Sudden fluctuations in the point discharge current magnitudes might easily be obtained by means of a cathode ray oscillograph, and synchronized records taken of the discharge current at two or more points situated on the storm track axis, and spaced about 3 miles apart. If the power lines should run at right angles to the storm, then the additional discharge points could advantageously be located along the line.

COMMON INDIAN GRASSES

An interesting volume which was "written at the request of the Forest Department of the United Provinces, India, who wished to have a manual which would enable forest officers to recognize the common grasses found in their forests, taungyas and plantations" has a much wider appeal and deserves a place among the books of everyone interested in the Gramineæ. Its low price should help to give it the diffusion it deserves*.

The author points out that the grasslands of India are what Tansley would call a biotic climax, and only exist and are maintained when there is a harmony between the climatic and biotic factors so as to prevent the formation of forest. As a consequence, forest officers need to regulate the grazing and burning of the grasslands under their management with care, since too little of either is as harmful as too much.

After a summary of the ecology of the grasslands of the United Provinces, the author briefly discusses the morphology of the Gramineæ and gives short but precise instructions for making detailed examinations of specimens. Two keys are included, the first being an artificial one dealing mainly with larger and more obvious characters and intended for the less specialized user. The second is based on C. E. Hubbard, and contains keys to all the genera and species with which the book deals, except that no key is included to the genera of the Maydeæ (possibly by an oversight) so that the user is not given a clue to the position of Chionachne and Coix. The author might have been bold and included them in the Andropogoneæ, since they are, as Bews says, little more than a sub-tribe of the former.

The rest of the work consists of descriptions of the species common to the United Provinces arranged alphabetically under the genera, each species having two descriptions, one of a more 'popular' type and the other of a more detailed technical character. The known and possible economic uses of each species are briefly mentioned. The ninety-two commonest grasses are described and the work is illustrated with sixty-four plates, most of the species being illustrated either by photographs of living plants or full-page drawings which show clearly their habit and more essential features, a task which is not at all easy with the grasses. The illustrations of Saccharum are especially good, though in some of the other genera a few more detailed illustrations of spikelet dissections would have been welcomed.

A number of small points detract from the work. Phraseology of the type "a feature which is made use of in separating these species", "The nodes are easily made out", "anker roots" (all on p. 19) and "Many species of the Andropogoneæ are collections of spike-like branches" (p. 20) tend to jar the reader. Again, the use of the word Gramineæ without its capital initial, twice in the introduction and occasionally elsewhere is not acceptable, especially as the author has no good reason for this and restores its capital later in the work. A number of plates have the bottom half an inch folded up as they are too large for the volume. This could have been avoided in most cases by a more careful placing of the figures, or even the titles.

However, these are only small defects: the book will be useful to anyone concerned with grasses and will provide good illustrations and descriptions of a number of most interesting tropical grasses not adequately treated in most text-books.

THE POTATO IN INDIA

The potato (*Solanum tuberosum*) is cultivated in India in the plains as well as in the hills. In the plains it is difficult to store the crop through the hot season. Hence seed in the plains comes from the hills or is imported. It is also difficult to hold potatoes in the plains in storage for table purposes owing to shrivelling, moth attack, wet and dry rots, high-temperature rot and sprouting. Potatoes after lifting will not sprout during a dormant period varying with temperature, variety and maturity at harvest.

Dr. D. V. Karmarkar and Mr. B. M. Joshi began experiments on the cold storage of the Indian potato in 1936, and their results are now published in Miscellaneous Bulletin No. 45 of the Imperial Council of Agricultural Research. The work was done under the Council's cold storage research scheme at Ganeshkhind Fruit Experimental Station, Kirkee. Below 35° F. dormancy was indefinitely prolonged. At 40° F. the maximum period of dormancy observed was nine months. Delay in placing potatoes at this temperature after harvest reduced the period of dormancy. There was no wastage at 40° F. or 35° F., but at lower temperatures, 30° and 32° F., the potatoes were injured after three months exposure. The injury was a blackening of the central tissues (black-heart).

The sprouting vigour of potatoes was not affected by extending the dormant period at 35° or 40° F. The growth and yield of crops grown from seed long stored at these temperatures may even be favourably affected. Black-hearted potatoes merely rot when used as seed.

This report, of which the main results are quoted above, is a sound piece of systematic scientific survey work of permanent value. It provides bed-rock data for agriculture and industry under Indian conditions, such as can only be acquired by years of organized effort. It is to be hoped that work of this character will be continued and extended.

Franklin Kidd.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public.)

Monday, February 16

Joint Meeting of Technical Societies arranged at the request of the Mines Department (in the Lecture Hall, Public Libraries, Sheffield), at 3 p.m.—Discussion on the Best Ways and Means of Promoting the Efficient Use of Fuel and Power in existing Industrial Plants under Present Conditions, and for Making Constructive Suggestions. (To be opened by Dr. R. J. Sarjant, Mr. H. C. Armstrong and Mr. Donald Wilson.)

Wednesday, February 18

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Sir John Russell, F.R.S.: "Post-War Agriculture in Great Britain".

Institute of Chemistry (London and South Eastern Counties Section) (at 30 Russell Square, London, W.C.1), at 4 p.m.—Prof. F. A. Paneth: "Artificial Radioactivity and the Completion of the Periodic System".

Thursday, February 19

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. H. J. Emeléus: "Fluorine".

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Mr. John Henry Gorvin: "Some Aspects of the Post-War Feeding of Europe".*

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Mr. J. M. Meek: "The Electric Spark".

Friday, February 20

Association of Applied Biologists (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Symposium on "Domestic Entomology".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Teacher of Physics (man or woman)—Principal, and Organizer of Further Education in Rugby, College of Technology and Arts, Eastlands, Rugby (February 20).

Waterworks Engineer and Manager—The Clerk to the Southport and District Water Board, Town Hall, Southport (March 7).

Advisory Entomologist for the Bristol province, under the scheme of the Ministry of Agriculture and Fisheries for the provision of technical advice for farmers—The Secretary and Registrar, Department of Agriculture and Horticulture, University, Bristol (March 9).

INTERNATIONAL ASPECTS OF RECONSTRUCTION

BEFORE the United States entered the War, the question of Anglo-American co-operation after the War and the implications of the fifth article of the Atlantic Charter were under discussion, and attempts were being made to face the more obvious difficulties which will confront the world in the years to come. Speeches by Mr. Attlee and Mr. Eden, as well as by Mr. Sumner Welles, revealed agreement not only on ultimate purpose but also on some of the measures by which those purposes should be pursued. Mr. Eden's broadcast following his visit to Moscow showed that the confidence entertained that the Soviet Government will fully support those purposes and measures is well founded. Moreover, the announcement made by President Roosevelt during Mr. Churchill's visit to Washington that all barriers to the full pooling of reserves between Canada and the United States would be removed, in accordance with the recommendations of the Joint War Production Committee of Canada and the United States, indicates that unity of command in the military, naval and air operations is being accompanied by equal unity in the economic sphere.

The tendency to unity has thus been greatly accelerated by Japanese aggression, and the disturbance in the economic sphere arising out of the immediate Japanese gains in Thailand, Malaya, the Philippines and Borneo raises problems in the sphere of production and war economy no less difficult than those offered to war strategy and tactics in the military or naval sphere. Only concerted economic policy can enable the available resources of the free nations to be devoted to the maximum production essential for the overthrow of the aggressor nations. The effort and sacrifices required of every citizen in the nations linked together in the defence of freedom must be inspired by a common policy, just as the efforts of the armed forces must be guided by a grand strategy.

The Washington and Moscow conferences have clearly laid the foundations for such a policy in the prosecution of the War, and there are equally clear indications that concerted measures and policy will not be laid aside immediately the War comes to an end. There may be differences of opinion as to the extent to which effort can at present be devoted to planning while the war effort has still to reach its peak, but Mr. Churchill's speech to Congress shows that the lessons of twenty-five years ago are impressed on the minds of our leaders; that it is no empty hope, in the words of his peroration, that "the British and American peoples will for their own safety and for the good of all walk together in majesty, in justice and in peace". The urgent needs of war are fashioning habits and weapons of co-operation that it would be the height of folly to destroy before we have determined how far or with what modifications they might equally serve the purposes of peace.

Much indeed has happened to give impetus to Anglo-American co-operation since Mr. Harold Butler wrote so wisely and presciently of it in his brilliant book "The Lost Peace". Our hopes both of economic revival and of a stable peace rest largely on the assumption by the English-speaking countries of their responsibilities for leadership in a bold and broad spirit. Such leadership, in which constructive statesmanship, stimulated by the strong social consciousness manifest in both countries and in the Dominions, with as general objective not only the restoration of economic stability but also the progressive improvement of standards throughout the Continent, may well prove the surest way of consolidating our friendship and understanding with the Soviet Government, and of enlisting a degree of willing co-operation from the neutral as well as Allied Governments which would not be obtained by any political appeal.

Given both the general objective and the broad lines of policy, there are still many difficult problems to be resolved before even at the end of hostilities effective action in their furtherance is possible. There is the problem of the future of Germany inherent in the realization of such a common primary aim as that of ensuring that German aggression shall never endanger the peace of the world. There is the related problem of the basis of a system of collective security on which Mr. Butler writes succinctly and sagely. There are all the immense problems of restarting the economic life of the world, the planning of post-war industry, the reconstruction of world trade and the like, with the further complications in the way of supplies and diversion or redistribution of industrial activity which the outbreak of war in the Far East has already necessitated.

If we are not to be overwhelmed by the magnitude of so stupendous a task or engulfed in non-essentials and irrelevances, the clear recognition of ultimate objectives and of fundamental principles is essential. Only so can we keep a sense of perspective when we come to the discussion of particular intricate problems, as Prof. J. B. Condliffe has done in a recent admirable analysis of the reconstruction of world trade*. In its absence, a certain air of unreality is attached to some of the discussions on the machinery of international organization like federal union. Mr. Butler suggests that the British and American peoples will go farther and faster along the road together if they keep their national identities, than if they try to merge them in a common government, which would not be palatable to either. What matters most is in fact not the form of the machinery or organization but the spirit in which it is used. The machinery can be modified or shaped to reach the desired purpose, given the spirit and the will, but in their absence any machinery may be wrecked or left idle. That, as Mr. Butler sees it, is essentially the lesson of the last peace. For lack of will and lack of vision, organization which might have served the peace was never really used, and unless we can bring to the service of the new order of security and peace something which will inspire the coming generations with the same enthusiasm and the same spirit of sacrifice that the defence of freedom now evokes in the youth of so many lands in war, that new order will not be durable. In the great tasks ahead of us we have to enlist all the idealism and devotion of the best men and women in the world. As Mr. Butler reminds us, love and charity are the only foundations upon which a real civilization can be built, and a real and lasting peace will come only when the notion of service is expanded beyond national boundaries and foreign policy is guided by Oliver Cromwell's maxim: "God has not brought us hither where we are but to consider the work we may do in the world as well as at home".

From such a constructive idealism our plans and our lines of advance must start. With it must go the readiness to learn the lessons of the past and to shape new methods if the old or traditional ones are inadequate to our purpose. The sober realism that tempers Mr. Butler's judgment on the lost peace must guide our handling of the reconstruction that will begin when the War ends, and of the planning and preparation that must already be put in hand. We cannot postpone this realistic attempt to organize the economic and political life of the world on broader, more international lines. We can avoid the mistake of thinking of the world in nineteenth-century terms, which did so much to lose the last peace, and we can profit from the failure of our first experience in organizing the world for peace by reading its lessons aright.

Fortunately, much of our experience in the War itself is forcing us to recognize not merely the economic unification of the world under the pressure of technical progress but also the political consequences, just as organization being established to serve immediate war purposes is equally apt to serve those of economic relief after the War. We should recognize further not only that some new form of international organization is indispensable if war is to be banished, but also with that the extent to which our civilization still owes its vitality, its culture and its rich diversity to the national ideal. Sound opinions on vital aspects of post-war policy must, as an admirable report of the Committee on Reconstruction produced by the Royal Institute of International Affairs, issued for private circulation, points out, be based on accurate information, and much in the programme of inquiries suggested by the committee is relevant to the winning of the War. No policy based on reason can be consistently and effectively applied in the absence of a certain degree of unity and steadiness in the public mind.

It is the function of the discussions and inquiries proceeding to contribute to the formation of sound public opinion as well as to the maintenance of moral and the provision of a basis for policy and action at the right time. In all this, preservation of a sane balance is a first essential. A sane balance between town and country is a prime requirement in national policy and stability. Social equilibrium is the first requisite of political stability, and ultimately the political, economic and social security of nations depends mainly on the extent to which the conjugation of their national policies is calculated to prevent international disorder and secure economic stability. The reconciliation of both national and international needs under the stress of war is being effected under our eyes. It will issue in a durable peace when men, as in science itself, are the servants of some purpose capable of satisfying their spiritual instincts and setting them on a new adventure in the quest of higher things.

DOMINATION OR RELATIONSHIP?

The Impulse to Dominate

By D. W. Harding. Pp. 256. (London: George Allen and Unwin, Ltd., 1941.) 7*s.* 6*d.* net.

ANY serious attempt to survey the psychological causes of war is noteworthy. But a work which leads logically and inevitably to the conclusion that war is inherent in our social pattern, relying as this essentially does upon dominative and prestige values, must challenge our best attention. In D. W. Harding's book, the author traces our individual failure in responsibility to two main problems. On one hand we need to become aware of certain unconscious tendencies which have fostered, and still maintain, the relation of domination or submission as the evolutionary ground-pattern in the development of our social and international relationships. On the other hand, the extreme complexity of the political issues of the great modern States makes it well-nigh impossible for the inexpert citizen, however intelligent, to participate responsibly in the crucial decisions of statesmanship. Since little can be done to reduce the latter factor to manageable proportions, the author wisely focuses attention upon those unconscious tendencies which can be largely modified through the cultivation of psychological responsibility.

Without minimizing the contribution which Freud and his followers have made in reducing the cause of war to the existence of infantile aggression and sadism, the author trims the balance by bringing into relief the basic dominative pattern which pervades our whole social atmosphere and which, therefore, must be regarded as a *representation collective* (Lévy-Bruhl), namely, an emotional preconception which everybody acts upon but nobody thinks.

Inasmuch as the author has called his work "The Impulse to Dominate", one could have wished for more enlightenment on the immense biological tail which civilized man has to draw after him in the realm of these archaic instincts. The general relation of the impulse to dominate to an underlying sense of insecurity is correctly stressed, but the perspective whereby this civilized mechanism is seen to derive its original dynamism from the primordial state whence, through the creation of communal solidarity, precarious solitariness was converted into a status of biological power and superiority, is strangely omitted. The author discusses Perry's anthropological evidence in support of the theory that violence is a cultural product and not, therefore, indigenous to our fundamental instinctual make-up. But Perry's contention that aggressiveness is a kind of diffusional accident is shown to be psychologically untenable, since it is impossible to believe that human beings could have built up a fundamental social structure which had no relation to their basal instincts. The fact that certain primitive tribes make violence their primary concern, while others, like the Eskimo, have produced an effective cultural breakwater against aggression, merely illustrates the difference of attitude with which the primitive mind has become adapted to a vital social problem. Perry's anthropological evidence is none the less significant. If the Eskimo have succeeded in creating a non-aggressive social pattern by a peculiar sense for communal responsibility, it is surely possible for us in the face of immediate necessity to cultivate the integrative pattern of relationship instead of the dominative. This fundamental change in attitude comes into the realm of the feasible, when it is borne in mind that the impulse to dominate is countered by its opposite, which might be called communal solidarity, or relatedness. When the one hypothesis leads us to the very brink of chaos, it is conceivable that a human migration towards the other pole will eventually create a sense of community among men in which the bare threat of domination will evoke instant response like that of the fire-alarm. The nation-wide discipline of fire-watching could even be regarded as a first step towards the development of a general attitude of responsibility in regard to the latent archaic potentialities in human nature. The author's insistence throughout the book upon the superiority of the integrative type of relation—based essentially upon a living feeling for human individuality—is supported by psycho-therapeutic experience. It is indeed in the cultivation of a relation of candour between patient and doctor, in which the distinctivenes and totality of the personality are unreservedly accepted, that the healing value lies.

From the psychological point of view, the only criticism of Harding's work that can be made (though a significant one) is the omission of any reference to the general dynamic determinants which are comprised in the various national myths. The myth of a people is more than a poetic heirloom. It is an incalculable storehouse of explosive energy, as we have seen to our cost in the resurgence of the tribal myth in Germany and Japan. The term 'pattern' is altogether too static and thin to comprehend the stupendous reserves of energy-potential which are evoked from the racial unconscious in times of national crisis. This omission is all the more singular inasmuch as the author's somewhat discursive review of the various regressive social phenomena of war-time, such as acquiescence, credulity, sadism, cruelty and sexual interest, demands just this comprehensive conception of the activation of the archaic unconscious to bring the total picture into a comprehensive focus. In point of fact, it was the abundance of similar evidence of archaistic social tendencies which led Jung in the first place to postulate the existence of a general unconscious. The author perceives the psychological inadequacy of the attempt to explain the war-time psyche from analysable factors in the personal unconscious, but he apparently recoils from the wider conception which could alone make it intelligible. The path which Trotter blazed during the War of 1914–18 in his "Instincts of the Herd in Peace and War" served us well for a time; but, since Trotter wrote, psychology has placed valuable tools in our hands which cannot be ignored.

Harding's work is compact and readable. If it has suffered from the exigencies of war-time economy, this necessary circumscription will make the book accessible to a larger public. It is a work that merits wide acceptance.

H. G. BAYNES.

THE ENDOCRINE ORGANS IN HEALTH AND DISEASE

Essentials of Endocrinology

By Dr. Arthur Grollman. Pp. xvi+480. (Philadelphia, London and Montreal: J. B. Lippincott Company, 1941.) 36*s*.

No science has developed more rapidly in recent years than that of endocrinology. This has been partly due to its great practical importance in relation to the study of disease, and it is noteworthy that many of the more important discoveries in this branch of science have had their origin in clinical observation. As Dr. Grollman points out, it is impossible to dissociate experimental from clinical endocrinology. Moreover, the latter can now be placed on a scientifically sound basis, for the organism is continually performing natural experiments the results of which can be followed up and correlated with other observed facts in such a way that conclusions of lasting value can be formed. It is the purpose of Dr. Grollman's book to bring together in one volume the results of all these observations and experiments for the average medical reader. At the same time, there is much in the work that makes a strong appeal to the general biologist.

The book is divided into five main parts. The first of these deals with the endocrine glands of the cranial cavity and more particularly with the hypophysis, which is a compound gland of great importance but not necessarily the 'master gland' of the endocrine system as some authors have conceived it to be. It is pointed out that certain disorders of hypothalamic origin have often been ascribed to the pituitary. Thus the well-known 'fat boy' condition may be hypothalamic. Nevertheless, the fact that stimuli of various sorts applied to the hypothalamus may affect the functions of the anterior pituitary, both positively and negatively, is evidence that hypothalamic lesions or defects may very often make themselves evident by interfering with pituitary function. In this part of the book the diseases ascribed to pituitary influence are well described and illustrated.

The second part deals with the branchiogenic organs and contains admirable accounts of the thyroid and parathyroid glands and the diseases arising from their dysfunction. The thymus is also included in this part, and after carefully considering the evidence, the author comes to the conclusion that none of the theories which have been put forward to explain its function are based on adequate experimental data or any plausible foundation. Some of the experimental evidence is contradictory as, for example, the claim that irradiation of the thymus in rats causes testicular atrophy, and the conclusion of Noel Paton that thymectomy tends to produce testicular hypertrophy.

Part 3 of the book is upon the endocrine organs of the abdominal cavity, namely, the 'islet' tissue of the pancreas and the medulla and cortex of the supra-renal. The pathology of these organs and their relationship to other organs and structures are well described, and much useful information is given concerning the treatment of the diseases connected with these organs. In dealing with the adrenals, there is a short account of their comparative anatomy throughout the vertebrates, but there is no mention of Swale Vincent, to whom much of our knowledge was due.

The fourth part, which concerns the reproductive system, is the least satisfactory in the book. Heape's original terminology used in describing the phases of the œstrous cycle is adopted with some modifications, but his name is not mentioned and the modifications do not make for increased accuracy. Thus, the anœstrum and diœstrum are not identical, and the latter is scarcely a period of rest since it is actually an abbreviated pseudo-pregnancy occurring only in polyœstrous mammals, and the distinction between these and monœstrous animals is not made. Ovulation does not necessarily depend upon coition in the cat, since many cats ovulate spontaneously during heat and are polyœstrous. Besides the rabbit and the ferret, the thirteen-lined ground squirrel (among rodents) does not ovulate without previously copulating, as shown by Foster. Moreover, among primates, both man and monkeys, there may be non-ovulatory diœstrous cycles and there is evidence that occasionally in women coition may induce ovulation. There is no such thing as a diœstrous period in the dog. Animals, such as most ruminants in temperate countries, which experience œstrus in autumn, usually bring forth in late winter or spring without any postponement of the development of the embryo. There is no evidence of a physiological law that the right and left ovaries of mammals produce ripe follicles which discharge their eggs alternately, but as a matter of actual fact this happens more frequently than not in the cow as recorded by Hammond and in the mare as observed by Day, and so probably may happen in other mammals. The placental theory of parturition does not explain the phenomena of pseudo-parturition as seen in the bitch, the rabbit and the marsupial cat. The absence of any account of behaviour cycles in relation to recurrent sexual phenomena is a noticeable omission.

The work concludes with a short fifth part on hormones produced from primarily non-endocrine organs, with notes on invertebrate and plant hormones.

About the general usefulness of the book there can be no question. F. H. A. Marshall.

SCIENTIFIC CHILD-STUDY

Child Psychology

Child Development and Modern Education. Edited by Charles E. Skinner and Philip Lawrence Harriman, with the collaboration of Amy F. Arey, Lawrence Augustus Averill, Lorin E. Bixler, Elden A. Bond, John W. Charles, Lester D. Crow, Raleigh M. Drake, Clyde Hissong, Clarence E. Ragsdale, Gladys Risden, J. J. Smith, Brian E. Tomlinson. Pp. xii+522. (New York: The Macmillan Company, 1941.) 12*s*. 6*d*. net.

The dominant note of this book, and the justification of review in the pages of Nature, is its claim, consistently maintained throughout, to adhere to a strictly scientific treatment of its subject. Poets and philosophers long held the field in the treatment of childhood, but since Darwin's time the man of science has joined them. Even the man of science has sometimes succumbed to points of view that could scarcely be called scientific, and the progress of child psychology has been from armchair speculation to the careful experimentation which is the sole concern of the writers of this book. They have written for a wide though a definite public—for parents, students of education, members of administrative staffs in schools, institutions and children's hospitals, and "those public-spirited citizens who may like to keep abreast of developments in this field". More especially, their purpose has been to meet the needs of teachers' colleges and university departments of education. No important aspect of child development has been omitted, not even the religious aspect. Some readers may in fact think that the scientific spirit is upheld to the point of quaintness when they read that "religious education can give human life dignity and worth through God-orientation".

As the title-page emphatically shows, the book is of highly composite authorship, there being no fewer than fourteen contributors. In this respect it differs from other recent and highly approved American books on the same subject, notably those of F. D. Brooks and Ruth Strang. The writers were carefully chosen for the specific contribution each was able to make. All of them have established connexions with leading institutions of higher education, and all of them are deemed to be qualified, by training and experience, to speak with authority. Equal care has been taken to prevent overlapping, and in an appendix the threads are pulled together by means of a full outline of the contents of the book. Extensive bibliographies enhance its value as a student's manual. By way of comparison with the well-known treatises of A. Gesell, J. Piaget and Susan Isaacs, it may be added that each of these is the work of one hand, and that each of them is in the main the result of original observation and experiment.

The range of topics covered by the book is so wide that it is only possible here to attempt a representative selection. On the vexed question of human instinct, for example, the authors are, on experimental grounds, led to a position which is neither that of the psychologist who made a list of fifteen hundred, nor that of the psychologist who found none at all. To maintain, says one of them, as McDougall does, that the human mind has a number of inherited tendencies that are the essential motivators of human striving has strong appeal to many even though others find the evidence unconvincing. It may be added that a general acceptance of McDougall's position seems to have led to fruitful results in the realm of applied psychology. On the subject of intelligence tests justifiably high claims are made for the brilliant work done by American psychologists, but with the equally justifiable warning that "unfounded generalizations, dogmatic assumptions, and unscientific attitudes have done much to destroy confidence in intelligence tests as they are now used and interpreted". The chapter on children's learning contains needed criticism of the half-truth that practice makes perfect: mere hammering away with no motive except to please parent or teacher yields little benefit, and we should never lose sight of the fact that learning often takes place with great suddenness—which is again a question of motive. There is an excellent chapter on the play life of children, but how odd it seems to anyone who has followed American studies in education produced during the past half-century to find that poor old Froebel is now not even mentioned! Odd, but no doubt inevitable, for though Froebel may have been in the main essentially sound, his writings cannot bear the test of scientific scrutiny.

This book on child study has been produced by a strong team of contributors, and it has features which differentiate it from other comparable books. It should take its place as a standard work on the subject. That it is addressed primarily by Americans to Americans is, at this time of day, a good reason why it should be well received on the other side of the Atlantic.

T. RAYMONT.

ENGINEERING DESIGN

Practical Design of Simple Steel Structures

Vol. 2: Girders, Columns, Trusses, Bridges, etc.: a Text-Book suitable for Civil Engineers, Structural Engineers, Road and Railway Engineers, and Students at Universities and Technical Colleges. By Dr. David S. Stewart. Second edition. Pp. xiii+289+11 plates. (London: Constable and Co., Ltd., 1940.) 16*s*. net.

Machine Design Drawing Room Problems

By Prof. C. D. Albert. Third edition. Pp. xi+441. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1940.) 21*s*. net.

In its second edition, Stewart's "Practical Design"—one of the series edited by Prof. Moncur and known as the "Glasgow Text-Books"—has been largely revised and rewritten to bring it into conformity with recent specifications. A substantial part consists of the detailed calculations necessary in the complete design of girders, columns, trusses, portals and bridges, and here an innovation has been introduced by arranging the figuring and the explanatory notes on opposite pages. This permits the calculations to be followed through consecutively and gives the young designer a guide to the proper method of setting out his own calculations in an orderly and logical sequence.

The book exhibits the dual purpose of developing the principles and applications of structural theory and of inculcating in the reader's mind the importance of the successive steps in the working up of a complete design. Against the risk of mere calculations being regarded too dogmatically, the author maintains a just proportion as between theory, practical knowledge and mathematical processes.

Prof. Albert's book treats of quite a distinct branch of engineering design, but it is evident that it too has been written from the point of view that practical knowledge is of the highest importance in design. It requires a sufficient knowledge of kinematics, mechanics and drawing, and offers, in conjunction with a parallel lecture course, the complete material for a practical course of instruction in machine design. The examples with which it deals include a number of unusual problems such as an arbor press, the frame of a punching machine, and a thrustor brake and thus afford a welcome change. The designs of these and other examples are fully worked out from initial specifications set out in much the same terms as they would be received in the drawing office and so present the method by which each problem is reduced to its elements and then worked up into the complete design. The latter part of the book forms a store of valuable data essential to the designer of machines and, for this alone, many will find it an almost indispensable item of drawing office equipment.

GALILEO GALILEI, 1564–1642

By PROF. H. C. PLUMMER, F.R.S.

IF there is something noteworthy in every tercentenary, in the conjunction of two such events in a single year there is something far more remarkable. The death of Galileo and the birth of Newton are important enough when considered separately. A great man has played his part and leaves the stage ; or another enters on a career no less brilliant. Both episodes are impressive ; that one followed the other within a space of twelve months adds to the significance of both. The two lives cover the whole of the seventeenth century and by themselves make it illustrious. The period between the birth of Galileo and the death of Newton was longer—no less than 163 years—running from the year which also saw the birth of Shakespeare in the reign of the Tudor Queen Elizabeth to the death of the first Hanoverian king. If that were all, it would be nothing extraordinary ; old Parr himself, who is reputed to have joined the reigns of Richard III and Charles I, covered nearly as long a span in a single life. But the age of Galileo and Newton was marked by an altogether unusual development of the human mind, and though this growth was far from being the work of two men, none contributed more powerfully to decide the extent and direction of its course than these two.

At the end of the sixteenth century, when Galileo was receiving his own careful and liberal education, the state of abstract science must naturally seem backward in comparison with what it became a comparatively few years later. There is indeed a manifest difference of scientific outlook between this and the following century, when the Paris Academy of Sciences and the Royal Society came into existence. Scientific method is applied with greater assurance, superstition is less evident and in fact the modern spirit has visibly grown in strength. Something of the change can be attributed to men like Francis Bacon, but more to Galileo and the abler among his contemporaries and followers.

Not that science, as distinct from medical knowledge, had failed to make considerable strides in Europe. After the deluge in which Greek culture had been overwhelmed, the scientific tradition passed into the keeping of the Arabs, to return to Europe about the thirteenth century. The subjects of serious interest were few, and chief among them was always astronomy. Indeed, a knowledge of this science had never been altogether lost ; the Venerable Bede had some familiarity with it, owing to the importance of the ecclesiastical calendar with its lunar and solar elements. But the Alfonsine Tables, which with modifications supplied Europe with astronomical ephemerides for about three centuries, were based on the Ptolemaic tradition preserved by the Arabs. The first attempt to understand the Ptolemaic system properly was made by Peurbach and Regiomontanus in the fifteenth century, and it was then that systematic astronomical observations were initiated. The next century saw the real advance made by Copernicus, though to Tycho Brahe's persistent observations astronomy owes an even greater debt for precept and example. From this point the main thread of astronomy passed through the hands of Kepler on the way to Newton, but the influence of Galileo, though less direct and less obvious, was no less important.

Like other sciences, astronomy was cultivated not merely because it appealed to intellectual curiosity but also because it satisfied human needs, first by supplying the data for astrology and later providing for the purposes of navigation. It owed its pre-eminence to its dependence on observation ; for though the art of observing developed with painful slowness from a primitive state, and the necessity of continuous application was realized as slowly, the case of those sciences which depended on experiment was far worse. Some knowledge of optics had been preserved by the Arabs, and with astronomy returned to the ambit of European culture. But it was of a geometrical kind, and it is symptomatic of its slow development on the experimental side that in 1600 the law of refraction was still unknown and was not discovered even by Kepler a few years later. A theory of sound was widely cultivated as part of the art of music, in which Galileo inherited great skill from his father, Vincenzo Galilei. After Gilbert's work, progress in electricity and magnetism was to prove slow and intermittent. In fact, natural philosophy was far from covering the whole extent of physics in Elizabethan days and for some time after. But chemistry was still more backward, though preserved among the lore of the Arabs and valued as alchemy ; even Newton, who made extensive researches in the subject, was mainly interested in the transmutation of metals.

Thus in Galileo's day, while the observational science of astronomy was beginning to advance by appropriate method, the experimental sciences lagged behind largely because the conditions for success were not understood. Quite naturally the change is first seen in optics. Galileo did not invent the telescope, but the barest hint of its possibility set him to work with his own hands ; and his example was followed. It is noteworthy that Galileo, Huygens, Newton, Descartes apparently and Spinoza certainly, were all practical opticians, who made lenses with their own hands. Here also is another change. Tycho Brahe, Galileo, Huygens, Boyle and Newton, who were distinguished by manual dexterity and a genuine taste for manipulation, were all far removed by birth from the artisan class. It was necessary to clear such occupations from social and intellectual prejudices alike, and the example set by Galileo in this direction was the more effective because his lectures as professor at Padua attracted an audience of the most distinguished.

As an astronomer, Galileo by the introduction of the telescope created a new type, in which he was to be followed by Huygens and surpassed by the first Cassini. He was not a painstaking observer like Tycho, and he was not a profound analyst like Kepler. But among other things he discovered the four principal satellites of Jupiter and the peculiar character of Saturn, the structure of the galaxy, and from observations of the solar spots he determined the rotation of the sun. Such achievements naturally brought fame and fanned his own vivid scientific imagination. The results were not altogether fortunate. They roused the implacable hostility of the fundamentalists, and it was not in Galileo's nature to adopt a conciliatory tone. He was a master of the satirical style and he used it with incisive effect.

The issue has been often misrepresented as concerned with the Copernican doctrine. But by 1616, when the "De Revolutionibus" was placed on the Index and Galileo received his first warning, astronomy had outgrown that stage, thanks to the work of Kepler. In fact, the problem of planetary motion was on the high road to solution, and the question between Galileo and his opponents was of a much more elementary kind. Whether Galileo used the actual words "Eppur si muove" may be doubtful, but they express the point in dispute exactly. It was not the nature of the earth's motion which was the subject of controversy, but whether the earth moved at all. Two years after the death of Kepler in 1630, the climax was reached and Galileo was condemned. The retractation extorted by an abuse of ecclesiastical power must have been a bitter pill to a pious man, but nothing was to be gained by obstinacy. *Magna est veritas,* and science needs no martyrs.

Apart from the struggle for freedom in the expression of scientific opinion, astronomy did not provide the field for Galileo's most important achievements. He was a mathematician according to the standard of his age and an acute observer, but above all he was an experimental physicist at a time when a pioneer in that capacity had an unequalled opportunity. His was among the earliest work in thermometry. But Galileo's real eminence rests on the experiments on which he founded the science of kinetics and the laws of motion. From the days of Archimedes little advance had been made in a knowledge of statics, if indeed the point reached in his wonderful discussion of the stability of floating bodies had been so much as remembered. But the notions entertained about the motion of a projectile were, before the days of Galileo, fantastic. By observations of the pendulum, of bodies in free vertical descent, of motion on an inclined plane and of projectiles under gravity, Galileo discovered the composition of velocities, the nature of uniform acceleration and the main principles of dynamics. For the first time the laws of motion were stated with fair precision, though the principle of momentum may have been defined more clearly by Descartes a few years later. A considerable advance was reserved for Huygens, who prepared the ground for Newton, but the essential steps had been taken by Galileo. There can be no happier example of the fruitful combination of well-contrived experiment with penetrating reasoning, for it was a virgin field which was brought under cultivation, and it is impossible to estimate the magnitude of the harvest in the form of practical benefit or in the domain of thought.

The effect on the progress of mathematics deserves particular consideration. Among the items of Greek culture which passed into the keeping of the Arabs, mathematics occupied an important place. They did more, as the very word 'algebra' suggests, and as the arithmetical scale of notation proves, than keep the science alive. But in the three or four centuries before Galileo's time the improvement had not been greatly accelerated on European soil. Geometry remained very much at the point reached by the Greeks, and few went nearly as far as that. Far more signs of life were shown by algebra, and Viète in France, Cardan in Italy and Harriot in England had made considerable advances, while Napier in Scotland had added the logarithm to the list of recognized functions. On the other hand, mechanics were confined to problems of statical equilibrium, and with this went a limitation of algebra to constant quantities and indeed almost entirely to positive constant quantity. Not until the consideration of the moving point and the relation of displacement in space to time was the notion of a variable quantity vividly presented. From that moment algebra and geometry developed into analysis. Thus the germ of infinitesimal calculus and all that is most important in modern mathematics can be traced to the demands of kinematical problems and therefore to Galileo.

Among his pupils two in particular deserve to be mentioned. There was Torricelli, mathematician and brilliant experimenter, who was the founder of hydrodynamics. There was also Cavalieri who, by developing the method of exhaustion of the ancients into the method of indivisibles, founded that Italian school from which James Gregory drew a part of his mathematical descent. Though not his pupil, Descartes was another who found in Galileo's work the source of those fertile ideas which affected the development of mathematics profoundly. Thus coordinate geometry was derived directly as the natural expression of the resolved motion of a point. It led not only to the representation of a curve by a relation between ordinate and abscissa, or from geometry to algebra, but conversely from algebra to geometry by the graphical representation of an equation. Hence the rapid development of the theory of equations which followed, together with the growing sense of generality when the relation of positive and negative quantity was appreciated.

In spite of his recantation, Galileo personified the hero as man of science. He was not the greatest astronomer of his time, nor was he the greatest mathematician. His chief distinction was due to the originality of his work in mechanics. In his life the hour and the man were combined, so that natural philosophy marched forward on a broad front, inspired by a single mind. To appreciate what this means, it is only necessary to consider what progress in mathematics, astronomy and physics was made in the short half-century 1642–92, and then to reflect how the germs of this advance in all branches can be traced to the one brain, Galileo.

In his search for scientific truth as he saw it, Galileo was clear-eyed and free from any scruple. He had expressed himself so candidly and his recantation was so plainly hollow, that it is hard to see what satisfaction his enemies could extract from his humiliation. Yet his attitude to science should not too easily be taken for granted, for it is very far from that which is accepted universally and without dispute. Perhaps the dangers of science have never been so widely proclaimed as at the present day, but they have always been felt, and by various methods it has been sought to mitigate them. Pythagoras and his followers found their method in the restriction of their knowledge to a band of initiates sworn to secrecy, who committed nothing to writing. Thus science was limited to the select and privileged few. The enemies of Galileo were actuated, so far as their aim was respectable, by the same motive—a dread of what would happen when Pandora's box was opened. But their remedy was altogether different from that of the Pythagoreans. What in effect they did was to maintain a system of error against a system of thought which was at least seeking fearlessly after truth. The result was disastrous, because the spiritual dangers which the more enlightened among them anticipated only too well could not be averted except by spiritual means, just as scientific error can only be met on the scientific plane. Changed as the circumstances may seem, the problem remains essentially the same as in the days of Pythagoras and in the days of Galileo. What would have been Galileo's answer can scarcely be doubted, for he was a great teacher as well as a great researcher. The function of science is to seek truth in its own sphere, regardless of consequences. At any stage, whatever the range of this knowledge won, it is necessary to adjust conduct in the light of the truth. The ethical problem is always the same; but the penalty of failure grows with the power which comes with increasing knowledge of the truth.

FOOD AND AGRICULTURE

At the afternoon session, on January 10, of the Conference on "Science and the War Effort", organized by the Association of Scientific Workers, Sir John Russell took the chair for the discussion of "Food and Agriculture".

Sir John Orr pleaded for the establishment of good will between different political parties in Great Britain and between the different countries of the world by all accepting Lincoln's revolutionary policy that countries should be governed by the people for the people. If Governments are going to govern for the people, their first duty is to provide the necessities of life for those people. These necessities are three: housing, clothing and health. We should plan for temporary housing for two or three years, and this should take precedence over the building of town halls, churches and schools. Our plans for food must be on a permanent long-range basis. We now know the human food requirements, and therefore we know the staple food supplies necessary for each country. More food than this would be waste; less, a waste of human life. We know that in peace-time this waste of human life occurs: in the United States only half the population enjoy sufficient of the protective foods to maintain them in health, and forty-five million people have a diet below the danger-line; and the standard of living in Great Britain is not much higher. If Governments adopted a food policy based on human needs, half the present disease and ill-health would be abolished. Such a policy could be used as a spear-head for trade prosperity and economic stability. Money would be needed; but such a policy would produce new real wealth, and we would be justified in creating credits. For this an international finance organization should be set up for trading in food. Scientific workers could get together to plan this and could say to the world: "We are planning for a post-war world in which every person will receive enough for health." Why have we not done so already? Great Britain should take the lead. We have done so much for the world; here is the next great step.

Prof. H. D. Kay discussed the application of science to the war effort in milk production and utilization. During the War the consumption of liquid milk has steadily increased: the consumption in 1941 was 25 per cent more than in 1938. Therefore, even if the supply of winter milk had remained at the pre-war level, there would have been a shortage during the winter of 1941. Actually, the supply of winter milk has only fallen by 2 or 3 per cent, and so most of the blame for the apparent shortage of milk this winter falls on the consumer. But this is no cause for satisfaction, since we have sacrificed eggs and bacon for milk; and we could have done much better than this had we applied science to dairying in Great Britain during the last few years. By the application of knowledge about breeding and feeding that is widely known—and applied in Denmark but not here—we could have increased the annual yield of milk by 30 per cent, and therefore could have supplied sufficient milk this winter with no increase in feeding-stuffs. There is a grave lack of training in scientific dairying among dairy farmers. With adequate training and the application of scientific principles we could attain what the climatic conditions of these islands and the character of these islanders allow us to attain—the best and most efficient dairying industry in the world.

Sir Daniel Hall considered the regeneration of farming as an economic industry. Farming in Great Britain is, by the admission of its own advocates, "down and out", and can only be kept going by isolation and protection from competition at a considerable cost in subsidies. These grants-in-aid have become substantial and by 1938 reached about forty million pounds a year; this figure must be considered in relation to the estimated value of British land, which amounted to £250 million—a very considerable proportion. The real objection to this policy is that the subsidies are not directed to improving the conditions or the methods of farming: we are giving alms instead of trying to set a poor man on the way to earning his living by removing the causes of his unsuccess. The majority of our farms are units too small to permit of the economies in working rendered possible by power machinery and of the improvements in methods that advances of science have shown to be practical. The two conditions necessary for the rehabilitation of farming are the expenditure of considerable capital in reconditioning the land, and then its apportionment into generally, but not exclusively, larger units. Since the landlords have proved unwilling to invest further in the upkeep of the land, this new capital can only be furnished by the State, and the State can only secure repayment by becoming the owner of the land. The dominant feature of the farming industry would then become large farming units working under conditions similar to those of other businesses, with a general manager, subordinates and other men with minor responsibilities to whom advancement was open. This nationalization of the land would regenerate farming as an economic industry and at the same time would bring into productivity much of the land, our national estate, which is now lying only partly utilized or even wholly waste.

The extent, causes and cure of malnutrition were dealt with by Dr. H. M. Sinclair. Evidence of the extent of malnutrition has been obtained from economic and dietary studies, and very recently from clinical and laboratory tests upon the population. These studies have not only shown the alarming prevalence of malnutrition but also defined the particular food factors most gravely concerned. Surveys have also shown to what extent the War has intensified the problem. Such surveys employing clinical and laboratory methods for the assessment of the state of nutrition of the population are now being made in various countries: in the United States (New York City, Duke University and Vanderbilt University), in Canada (Toronto), in France (Marseilles) and in England (Oxford Nutrition Survey). The study of groups of people living on diets of different quality has shown the effect of food upon health and physique. The incidence of different infectious diseases, for example, tuberculosis, bronchitis, diphtheria, in people of different income-groups is probably due largely to malnutrition, though other factors such as overcrowding are also concerned. Supplementing the diet of school-children has shown the effect of good food upon growth and strength; and recent work in Toronto has indicated that with proper feeding of poor women, maternal and infant mortalities can be greatly lowered. Very recent work with human volunteers on experimental diets has shown that slight deficiency of particular vitamins produces vague ill-health: lassitude, weakness, fatigue. The primary cause of malnutrition is poverty. Secondary causes are ignorance and the decreased availability of familiar foods. The cure lies mainly in increasing the consumption of protective foods. In peace-time, therefore, public health planning demands an increased production of those things that scientific agricultural planning encourages. The War has intensified and changed the problem; and in the period immediately following the War there will be world-wide famine. The British Empire, the United States, the U.S.S.R. and China should set up now an international committee of men of science to plan the adequate feeding of the allies during the War, and of the world when victory has been secured. The resources of agriculture alone are insufficient for both these tasks, and must be supplemented by new dietary sources of vitamins, minerals and possibly protein. In this task chemists have an important part to play. By their united action, men of science can abolish malnutrition and produce the greatest advance in public health since the introduction of sanitation.

Prof. F. G. Gregory emphasized the part that vernalization could play in increasing agricultural production. For example, it allows a catch-crop to be taken between the two main crops in the rotation, thereby permitting a much greater production of food from the land. The technique was first used in the U.S.S.R. and has been enormously developed there, but has attracted little attention in Great Britain. A recent Russian memorandum gives full details of the latest advances in vernalization.

Other examples of the failure of agriculture in Great Britain to make the best use of the results of research were given by Dr. A. Walton. Such research has mainly been directed to obtaining a priority value for the progressive farmer, who represents a very small proportion of farmers. Research is run by a complicated system with no less than seven bodies concerned: Parliament, the Treasury, the Development Commissioners, the Ministry of Agriculture, the Agricultural Research Council, the institutes of research and the research worker. The result is that there is a tremendous delay in the research worker obtaining the grant required for his work; and the research workers themselves, particularly the younger ones who actually do the work, are scarcely represented on any of those bodies. Fortunately steps have recently been taken to short-circuit this delay by the appointment of the Agricultural Improvement Council. In the rationing scheme for feeding-stuffs, and in artificial insemination, there has been lamentable delay. Dr. Walton's own work on the latter subject was repeatedly reported to the Ministry, and the Agricultural Research Council took the view that it was concerned with research and not with practical applications; when war broke out the reverse position was adopted—that artificial insemination was not immediately practicable, and therefore could not be given subsidies in any way. The result is that Great Britain, for the lack of perhaps a few hundred pounds expended six years ago, has lost some millions that might have been saved, and we are now more than ten years behind the U.S.S.R. in this matter.

From the chair, Sir John Russell drew the threads of these addresses together. In days gone by the conservation of the soil, and especially the preservation of the soil, was the farmer's sole purpose. He thought not only of to-day, but also of to-morrow; the soil had to last, and had to be available for the next generation. Then followed the long years' policy of cheap food, the farms lost numbers of workers, and those who came back to farming had no experience of arable farming. The soil decreased in fertility. Our system of agriculture postulated peace, because our diet required 1·6 acres a man, and therefore food had to be imported. But in Germany the national dietary had been adjusted to require only 1·1 acres a man, and so they could feed the majority of the population without importing food. We should aim at producing unstinted bread, potatoes and vegetables, and as much milk as possible. Wheat is compact, easily produced and easily transported; grain requires nitrogenous fertilizers which are available in this War. Germans consume twice the potatoes we do; and whereas our crop was previously produced in localized areas, it must now be distributed over the country to facilitate transport and increase consumption. But this scattering will introduce new problems such as the control of pests. We must, however, tackle and reduce the enormous waste produced by insect pests. The wire-worm has already done a great deal of harm in this War; it did much harm in the War of 1914–18, but it was not studied in the interval of peace. The flea-beetle destroyed winter crops needed for the production of mutton. Also we must tackle the rats—often the most intelligent things on the farm. Improvements in agriculture, brought about by increased research and the application of research, will help the spread of adequate nutrition and do much to abolish the evil of malnutrition.

PREPARATION OF PERSPECTIVE DIAGRAMS

By DR. G. D. HOBSON

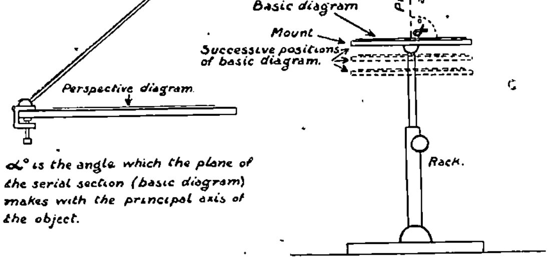
Imperial College of Science and Technology

CONTOURED maps, serial sections, or plans and elevations, are capable of providing much detailed information about the form of regular or irregular bodies and surfaces. It is, however, not always possible, from an examination of such diagrams alone, readily to visualize the real shape of the surface and the relationships of the various parts, as the process of mental integration of the series of basic diagrams can often only be carried out after a prolonged study. Moreover, the formation of a complete mental picture, which can be easily used, may not always be possible. To overcome this difficulty, models of the surface may be constructed from the basic diagrams, and in most respects these constitute the ideal solution of the problem, since they can be viewed from many angles with ease. Unfortunately, such models are generally expensive and tedious to make[1,2,3,4], besides being fragile and not easily duplicated, and, when large, not portable. As a consequence, resort is frequently made to diagrams in which it is attempted, with varying degrees of success, to convey an impression of the third dimension. These diagrams have some of the virtues of models, and at the same time they are readily reproduced and stored.

Diagrams which give an impression of solidity and are prepared from contoured maps, serial sections or plans are of three types. The simplest types are orthographic projections, either on the plane of the basic diagrams or on some plane perpendicular to it. Their preparation has been described by Pusey[5], and their effectiveness depends to a large extent on the skilled use of shading. Wilson[6] has given an account of the production of the second or isometric type of diagram for mine workings. Such diagrams may be made by simple geometric methods, or with the aid of one of the instruments described by Lobeck[7] or de Sitter[8]. Although valuable, isometric diagrams have in many instances an unnatural appearance. The perspective diagram, the third type, has a more natural appearance, and is therefore to be preferred. Perspective diagrams can be constructed by geometrical methods[9,10,11] and McPherson[11] gives a computational method for transforming the co-ordinates of points on the surface to co-ordinates of points on the perspective diagram. None of these methods is wholly satisfactory for highly irregular surfaces, for a choice has to be made between plotting comparatively few points accurately and sketching between them, and laboriously plotting a very large number of points in order to define a line almost continuously.

Recently an instrument has been devised for the mechanical production of perspective diagrams from contoured maps[12], but it will not be easily or cheaply constructed, a drawback which is probably shared with any other mechanical devices which may have been invented. However, if a camera lucida (or other suitable optical arrangement) and a mount for the basic diagrams, set on the end of a graduated rack, or its equivalent, are available, perspective diagrams can be prepared by quite a simple method. A search of some of the scattered literature on the preparation of perspective diagrams has not revealed any previous reference to the method, in spite of its general applicability.

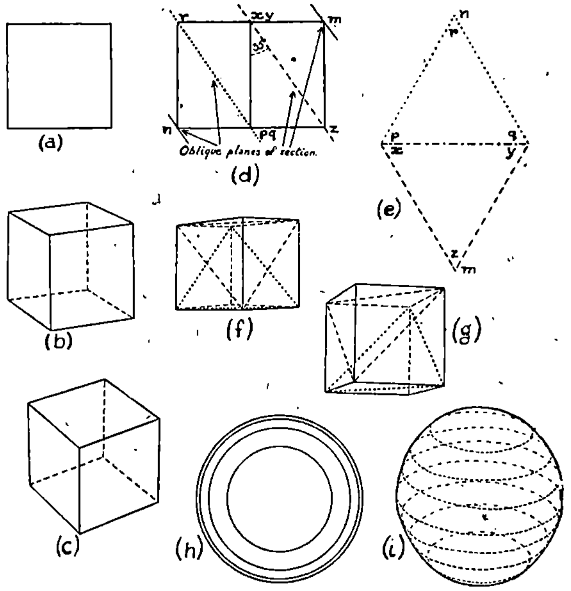
Fundamentally, the method merely consists of setting the serial sections or contours successively in the correct relative positions which they would occupy in or on the body, and drawing their appearance from a pre-determined viewpoint, with the aid of a camera lucida. In effect, the basic diagrams are made to describe the surface of which they are sections. The basic diagrams—contoured maps, serial sections or plans—if not of manageable dimensions, are first transformed to a readily usable size, that is, to a size in which the necessary lines can be seen and drawn without difficulty when viewed through the camera lucida. In the case of serial sections, it is not usually possible to transfer them to a single sheet of paper without leading to confusion, and hence they must be piled in their correct order and register. (In searching for published serial sections suitable for testing this method, it was found that they are figured without registration marks being included. Consequently, they are not immediately available for reconstructions either as models or as perspective diagrams. The value of such published sections would be increased by the inclusion of registration marks.)



$\alpha°$ is the angle which the plane of the serial section (basic diagram) makes with the principal axis of the object.

Fig. 1.

ARRANGEMENT OF CAMERA LUCIDA, RACK AND BASIC DIAGRAM FOR DRAWING A PERSPECTIVE VIEW OF AN OBJECT WITH ITS PRINCIPAL AXIS APPEARING TO BE VERTICAL.



The correct viewing distance is that with the eye twice this marked distance from the plane of the paper. The eye-level differs for the various perspective diagrams. In the case of (i), the top of the diagram should be two-thirds of the marked distance below the eye-level.

Fig. 2.

(*a*) Basic diagram for the construction of a cube in perspective. The plane of section is at right-angles to the principal axis of the cube.

(*b*) Perspective cube with axis vertical, derived from (*a*) by setting the basic diagram at two levels differing by a distance equal to the length of the side of the square.

(*c*) Perspective cube with inclined axis, and derived from (*a*). Instead of the basic diagram being horizontal as in constructing (*b*), it was tilted.

In making (*b*) and (*c*), the basic diagram was supported in a plane at right-angles to the axis of translation of the rack.

(*d*) Side elevation of symmetrically placed cube, showing the parallel planes of section.

(*e*) Basic diagram obtained by drawing, in their proper positions, the oblique serial sections taken along the planes shown in (*d*).

(*f*) and (*g*). Perspective cubes derived from (*e*). The same basic diagram could have been used to give perspective cubes for the types of positions shown by (*b*) and (*c*). The projections of the serial sections are marked to correspond with the appropriate parts of the basic diagram (*e*). In making these reconstructions, the basic diagram was supported in a plane making an angle of 35° with the axis of translation of the rack.

(*h*) Basic diagram for perspective sphere. The circles, in decreasing diameter, represent sections through a sphere at the following levels, measured from the lowest point on the sphere: $\frac{1}{2}R$; $\frac{3}{8}R$ and $\frac{5}{8}R$ superimposed; $\frac{1}{4}R$ and $\frac{3}{4}R$ superimposed; $\frac{1}{8}R$ and $\frac{7}{8}R$ superimposed, where R is the diameter of the sphere. (*i*) Perspective sphere reconstructed from (*h*). The drawings used to define the sphere's outline are shown dotted.

If the basic diagrams are on planes at right angles to the principal axis of the object, and it is desired to make this axis appear vertical in the perspective

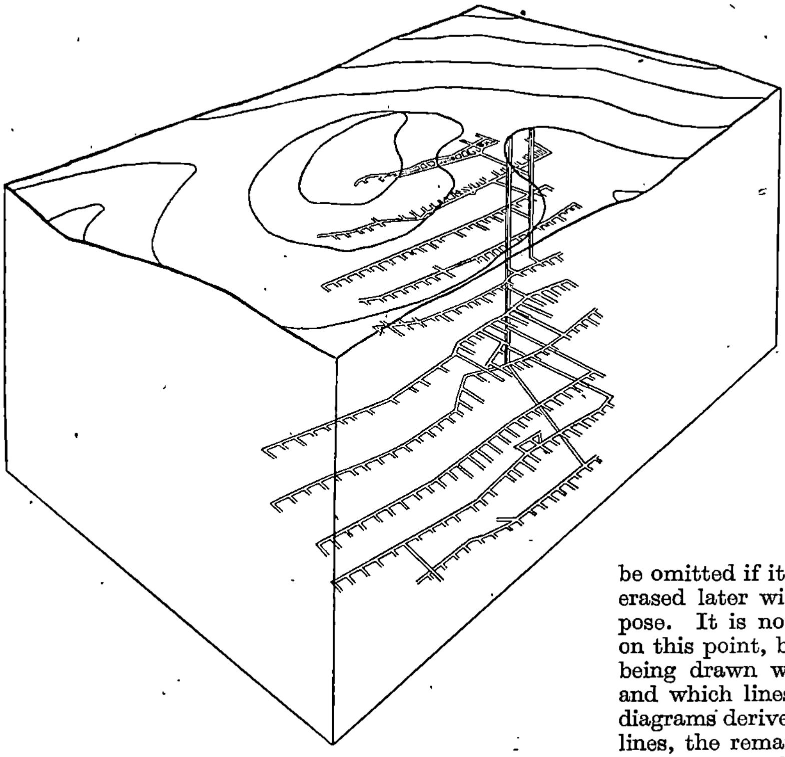


Fig. 3.
MINE WORKINGS, DRAWN FROM MINE PLANS.

diagram, the basic diagrams are mounted in a plane at right angles to the direction of movement of the rack and the latter is set to give vertical motion (Fig. 1). Having erected the camera lucida, the rack with mounted diagrams is placed so that the mid-point of the diagrams is at the appropriate distance from the camera lucida for the lens employed. The diagrams are then racked to a position at which the diagram of the highest contour or section can be seen satisfactorily through the camera lucida, and the basic diagrams are suitably oriented with respect to the viewpoint. Next the highest contour or the topmost serial section is drawn on a fixed sheet of paper while looking through the camera lucida. After removing the topmost section, if serial sections are being used, the mount is racked down by a distance corresponding to the contour interval or the distance of the second serial section below the top section, the distance being in terms of the scale of the maps or sections. The second section or contour next to the highest is now drawn, and all subsequent sections or contours are dealt with similarly. For some purposes it may be desired to magnify the vertical scale in the perspective diagram, although such magnification is not recommended as a general procedure, and should always be noted when used. N-fold magnification of the vertical scale involves racking down the mount N times the true equivalent of the contour or section interval.

In the case of maps, the intersections of roads, rivers or other features with a given contour are marked when that contour is drawn. Afterwards the points of intersection are connected together with the assistance, if needed, of intermediate points obtained by racking the map to inter-contour levels and marking the position of the feature at the corresponding height on the map.

In dealing with large diagrams or a series covering a considerable vertical range, the image of a diagram or of parts of one may not be perfectly focused on the paper on which it is to be drawn, but as a rule no difficulty will be experienced in drawing the image, and a slight uncertainty does not appear markedly to affect the final perspective impression.

After all the basic diagrams or contours have been converted to perspective projections, the outlines of features on the object are filled in by connecting related points, and those parts of the projections of the basic diagrams which are masked by the presence of part of the object between them and the viewpoint are erased or dotted as required. In making the camera lucida drawings, parts of the diagrams may be omitted if it is apparent that they will have to be erased later without having served any useful purpose. It is not possible to give brief general rules on this point, but a little consideration of the object being drawn will indicate broadly which lines will and which lines will not be needed. If perspective diagrams derived from maps are to retain the contour lines, the remainders of the contours are marked in more heavily, but with other objects the remaining lines of the projections of the basic diagrams should be used as a guide in shading, some direction of illumination being assumed, and ultimately erased, as a rule. Shading is of prime importance, for it removes the impression of flatness which is apt to persist in line drawings of curved bodies, permits the indication of features which cannot be shown by definite lines, and enhances the impression of solidity even in the cases of drawings of bodies bounded by sharp edges and plane surfaces.

If it is decided to 'look down' on the object, that is, to incline towards the observer the upper end of the principal axis which is ordinarily depicted as vertical, the rack, with the plane of the mount and

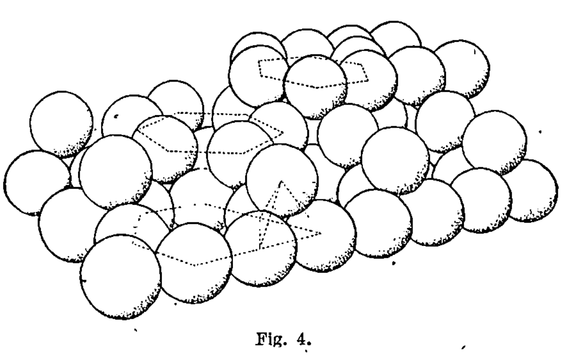

Fig. 4.
PERSPECTIVE DIAGRAM OF SET OF SPHERES SUCH AS MIGHT BE USED TO SHOW THE SPATIAL RELATIONSHIPS OF THE ATOMS IN A CRYSTAL.

Parts of the upper two layers have been removed. While no attempt has been made to depict a mineral species, it may be noted that the tetrahedral relationship of the spheres forming the bottom two layers would be that of the fundamental SiO_4 unit if a small sphere representing silicon were to be placed in the centre of each tetrahedral unit. The diagram was drawn from a plan view of the contoured spheres and a knowledge of the separation of the different layers of spheres vertically.

diagrams still at right angles to the direction of its travel, is inclined with its upper end towards the camera lucida. The procedure is then exactly as described above, and the same contour intervals are measured along the rack as when the principal axis was supposed to be vertical.

With sections cut at right angles to the principal axis of the object, the perspective diagrams which can be drawn with that axis vertical are those in which the object is appreciably below the eye-level (Fig. 2, *b*, *c*, *i*), for it is not possible to see the basic diagrams well when they approach the edge-on position. Perspective diagrams could also be drawn for the object above the eye-level, if the basic diagrams were mounted so that they could be viewed from below. However, if sections are available which, instead of being at right angles to the principal axis, are oblique to that direction, perspective diagrams can be drawn for the object in positions above, below, or intersecting the eye-level, provided that the obliquity is sufficient (Fig. 2, *b*, *f*, *g*).

In order to prepare perspective diagrams from oblique sections, the basic diagrams are mounted on the end of the rack at the same angle as they bear to the principal axis of the object. The construction is carried out in the same manner as for sections cut at right angles to the principal axis of the object. But it should be noted that the shift of the rack between drawing consecutive basic diagrams is equal to their separation along the principal axis, not to their separation at right angles to their own planes. The basic diagrams must be piled so that the points where the vertical axis cuts the separate sections are superimposed. As before, any orientation is possible which leaves the basic diagrams adequately visible. This modification is practicable with serial sections in palæontology, botany and zoology, but not directly with maps, since the contours are drawn on planes at right angles to the vertical (principal axis). Topography and geological structures are almost invariably assumed to be viewed from above for the purposes of diagrams, and as a result, the limitation in contour drawing is of little consequence.

In constructing perspective diagrams of complicated objects with closely spaced sections, the camera lucida drawing of each basic diagram should be in a different colour in order to reduce confusion, and the marking of features may be carried out by degrees, instead of after all the perspective projections of the basic diagrams have been drawn. It may even be necessary to make the camera lucida drawings on separate sheets of tracing-paper which are superimposed for the final reconstruction, or alternatively to make the drawings on sheets of ordinary paper provided with reference marks for use in tracing the essential parts from each sheet. The use of colours in the perspective diagram, with or without transparent overlays, may prove advantageous in showing internal features in complicated objects.

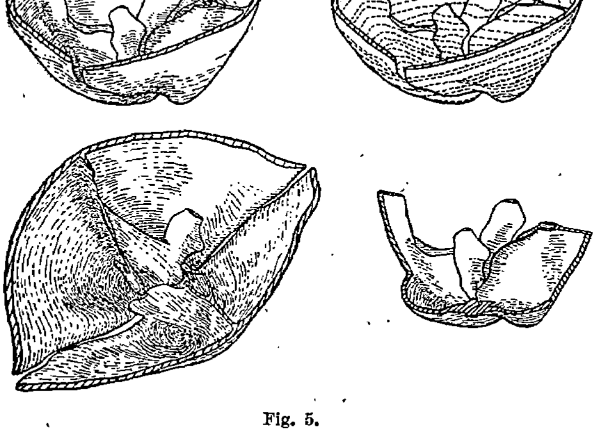

Fig. 5.

Parastrophina hemiplicata. PERSPECTIVE DIAGRAMS PREPARED FROM DRAWINGS OF SERIAL SECTIONS KINDLY LOANED BY DR. J. K. S. ST.-JOSEPH.

Comparison should be made with figures in the *Geological Magazine* (5), 78, 381 (1941). The upper right-hand diagram includes the contours which were used as the basis for shading.

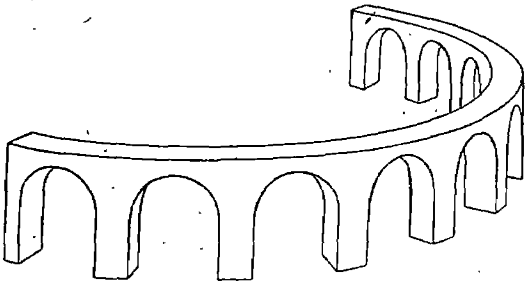

Fig. 6.

PART OF A CIRCULAR ARRANGEMENT OF ARCHES.

The drawing was prepared from the plan of the arches and a knowledge of the height and form of the individual arches.

Some experimentation may be necessary before the most satisfying view is obtained. Moreover, since the usual aim is to give a picture of the whole rather than of the details, it is more important to get the salient features in their proper relationship, balanced by a skilful selection of useful detail, rather than to copy all the detail meticulously, especially if it can only be fully appreciated on the original maps or sections, or if it will encumber the final drawing.

The size of the perspective diagram which can be produced directly by the present method is determined by the need to be able to look through the camera lucida and draw an image which is reasonably well focused. Diagrams about 25 cm. × 25 cm. are probably of the maximum size comfortably producible for a viewing distance of 30 cm. The method is probably used to the greatest advantage for approximately equi-dimensional objects, or those with a small vertical dimension and the other dimensions larger and about equal. Drawings of internal structures can be made with the same ease as those of the outer form. If models were used, such drawings would generally require either the construction of a special model or the partial destruction of the normal type of model.

For some types of basic diagrams optical arrangements other than the camera lucida may be used for producing the perspective views of the separate basic diagrams; for example, a photograph or camera obscura drawing may be made for each setting of the basic diagrams. In the case of photographs, the significant parts are afterwards traced, suitable reference marks being used to get correct super-imposition for each photograph. The fundamental idea of manipulating the basic diagrams is applied exactly as described for the camera lucida.

Perspective diagrams can be prepared by this method, or by means of Bain's perspectograph[13], for any body for which a series of parallel sections can

Basic diagrams	Perspective diagrams
Contoured maps.	Topographical perspectives, with drainage, roads, etc.
Stratum contour maps	Form of geological horizons, faults, etc.*
Mine plans.	Mine workings and the form of ore bodies (Fig. 3).*
Spatial relationships of atoms in a crystal, obtained from X-ray diffraction patterns.	Perspective diagrams of the positions of atoms in a crystal, with coloured or differently sized spheres representing the various kinds of atoms (Fig. 4).
Serial sections.	Palæontological, botanical or zoological objects (Fig. 5).
Plans for the various levels at which a change in form occurs.	Architectural and engineering structures (Fig. 6).
Sections for significant levels.	Engineering objects ; for example, pieces of mechanism, castings, lay-out of pipes, etc.
Series of curves relating two quantities, for different values of a third quantity.	Perspective view of the surface represented by the relationship between the three quantities, with or without the separate curves.

* These may obviously be combined with topography.

be obtained or easily constructed. The accompanying table summarizes some of the possibilities.

In conclusion, it may be recalled that perspective diagrams are prepared for one eye at a definite point, and hence they may not appear satisfactory even though accurately constructed, when they are viewed with both eyes and from a point appreciably different from that for which the diagrams were made. Consequently, the normal reading distance should be borne in mind when preparing perspective diagrams for publication. If they are drawn for a very different viewing distance, that distance should be indicated. Furthermore, in the case of very small objects involving the use of greatly enlarged sections, the resultant perspective diagrams may be somewhat unfamiliar because of the different angle subtended at the eye.

OBITUARIES

Prof. R. S. Seton

THE death of Robert Sutherland Seton in Leeds on January 12, at the age of seventy-four, will be deeply regretted among the agricultural educationists in Great Britain. Seton was a native of Watten in Caithness and became a student of agriculture at Edinburgh under the late Prof. Robert Wallace: he graduated in 1894 and then studied chemistry for a time at the Royal College of Science in London. After holding appointments at the Downton Agricultural College and the Harris Institute, Preston, he was appointed in 1900 to the chair of agriculture at Leeds, where he remained until he retired under the age limit in 1932.

As a teacher he set a very high standard in the personal attention that he gave to each student and to each applicant for admission to the agricultural courses. The written information on the form of application meant little to him ; he had to get hold of the individual and discuss with him in detail the problems of his training and his career. There will be many agriculturists at home and abroad who retain vivid memories of these first discussions and who are grateful for their beneficent influence. The successful careers of so many of his students will be in large measure due to the thoroughness with which he discussed their training with them at the outset and to his insistence on adequate practical experience before entering upon a university course.

While Seton was responsible for designing and carrying out many important field experiments, it was never his policy to adopt a special sphere of research as his own personal life-work. He was far more concerned to stimulate and encourage the work of his colleagues in all the various sections of his diverse department. He maintained a uniform interest in all branches of agriculture and the agricultural sciences, and no hour of the day or night was to him inopportune for the discussion of any piece of work going on in the department. He gave his time and help to his colleagues in this way without any concern for the recognition of his personal contributions to the work.

In the development of the advisory services of members of the staff among Yorkshire farmers, Seton did pioneer work. An advisory service whereby specialist officers are available to farmers is now established uniformly throughout Great Britain, but such a service was long before in existence in Yorkshire under Seton's direction and inspiration. In directing his colleagues in this advisory work he brought not only valuable help to the farmer but also considerable inspiration to the teaching in the Department by keeping lecturers in touch with practical problems.

The development of the Agricultural Department in Leeds in its teaching function, its research work and its advisory service will always remain as Seton's life-work. To this work he devoted an enthusiasm that remained undiminished to the end. Nevertheless he found time for other interests. The Board of Greenkeeping Research, on the committee of which he served, will remain indebted for the help he gave, and his influence was brought to bear upon agricultural education in Great Britain as a whole through his long and active membership of the Agricultural Education Association.

Seton will be remembered with great personal affection by all who worked with him and studied under him. N. M. COMBER.

Prof. J. P. d'Albuquerque

PROF. JOHN PEDROSO D'ALBUQUERQUE, who died at Ilfracombe on December 20 at the age of seventy-six, was a brilliant chemist.

From the City of London School he went up in 1885 to St. John's College, Cambridge, where he was for a time demonstrator to Prof. Liveing. Scholar, exhibitioner and Wright Prizeman, d'Albuquerque took first class honours in chemistry in Part I of the Natural Sciences Tripos in 1887 and again in Part II in 1889. It was predicted that he would attain high academic distinction in England; but he preferred to migrate to Barbados, having been offered in 1890 the post of Island professor of chemistry there in succession to Prof. Harrison, who had been transferred to British Guiana. Harrison and J. R. Bovell had recently discovered (or, as some say, rediscovered) the fertility of sugar-cane seed and had successfully raised seedling canes. This work was continued by d'Albuquerque in collaboration with Bovell, and many new varieties of cane resistant to disease which was decimating the Bourbon cane were made available. In 1898 d'Albuquerque assumed the additional duties of consulting chemist to the newly formed Imperial Department of Agriculture. As chemist-in-charge he was responsible for carrying out (still in co-operation with Bovell) an extended programme of experiments and research. Many published reports recording the results remain as a monument to his and his fellow-worker's industry, which exercised a profound influence on cane cultivation throughout the sugar-producing world and laid the foundations on which the present West Indian Cane Breeding Station in Barbados was built.

Between 1899 and 1909, d'Albuquerque acted as Imperial commissioner on numerous occasions. In 1910 Barbados seceded from the Imperial Department. A separate Department of Agriculture for the Colony was constituted with Bovell as head, and, after his retirement in 1925, d'Albuquerque was appointed director of science and agriculture. In that capacity he attended the Imperial Agricultural Conference in London in 1927. His activities were many. Besides performing the onerous duties of director, he remained in charge of science teaching at Harrison College, the Lodge, and Combermere School, and several generations of boys profited greatly from his teaching. He also reorganized the Government analytical laboratory, which was concerned not only with foods, drugs, and public health, but also commercial sugar analysis, a work which increased enormously as, thanks to his precepts, the planters became more scientifically minded. It is not too much to say that d'Albuquerque succeeded in revolutionizing the ideas of the planting community on the place and value of scientific research in tropical agriculture.

When in 1928 d'Albuquerque retired on account of failing health, Barbados was the poorer by the loss of a prominent scientific worker and a genial resident, who for nigh on forty years had identified himself with the social and official activities of the island which he had made his home.

d'Albuquerque was a keen Freemason. He was District Grand Master of the Barbados Lodge from 1906 until 1930 and a founder of the Caribbean Lodge. He was married in 1891 to Miss Beatrice Alice Langley, who with a son (a barrister-at-law) and a daughter survive him.

ALGERNON ASPINALL.

We regret to announce the following deaths:

Dr. Elsie C. Parsons, president of the American Anthropological Association, on December 19, aged sixty-six.

Prof. Hans Schinz, formerly professor of botany in the University of Zurich, aged eighty-three.

Prof. Virgilio Tedeschi, professor of biological physics in the National University of La Plata.

NEWS and VIEWS

Central Planning Authority

MR. ARTHUR GREENWOOD, Minister without Portfolio, announced in the House of Commons on February 11 that a Central Planning Authority is to be set up. Duties in connexion with town and country planning at present exercised by the Minister of Health will be transferred to the Minister of Works and Buildings, whose title will be changed to "Minister of Works and Planning". The newly styled Ministry will guide local authorities and will exercise the powers to be conferred by legislation arising out of the acceptance by the Government of the first report of the Uthwatt Committee, laying down the general principles to which planning must conform. The Secretary of State for Scotland will exercise corresponding powers in Scotland. The two ministers concerned will be assisted by committees of senior officials of the Departments on which their activities will impinge in order to secure consistent action throughout the country. By this means the Government hopes to secure the most appropriate development and use of the country, taking into consideration the recommendations of the report of the Royal Commission on the Distribution of the Industrial Population, and also the need for avoiding measures which would interfere with the over-riding aim of raising the standard of living to the highest possible level.

Lord Reith, who now becomes Minister of Works and Planning, made a similar statement in the House of Lords, amplifying it with an account of steps which are already being taken. The decision now announced, he said, implements the Uthwatt Committee's assumption of the early establishment of a central planning authority. Meanwhile, that Committee is now making an objective analysis of the subject of the payment of compensation and recovery of betterment in respect of public control of the use of land. Lord Reith's consultative panel has also been active. The Director General of the Ordnance Survey, Dr. Dudley Stamp and Prof. Eva Taylor are preparing maps for planning, showing physical features, land uses, movements of population, industry and communications. Lord Justice Scott's committee considering conditions which should govern constructional developments in rural areas is at work, as is also the inter-departmental committee co-ordinating the views of the various departments concerned. The latter has prepared a Bill to give effect to the recommendations of the Uthwatt Committee, and has considered long-term planning, the preservation of amenities, etc. His own group of special assistants has been responsible for the work of this committee and for the research which is the essential foundation of any scheme of national planning. In addition, the supply and standardization of materials have been under consideration, of necessity from the point of view of the war effort, but also with regard to the post-war implications. The central problem is to achieve the maximum benefit to the country of limited land resources available.

The Wartime Social Survey

ONE of the most recent developments in State research in the field of sociology is the Wartime Social Survey. After an initial period of growing pains, this Survey is now emerging as a valuable machine for conducting any type of inquiry capable of investigation by the method of interviewing samples of the population. Two Government Departments, the Ministries of Information and Food, required a market research machine for investigating the effects of their advertising. When the Wartime Social Survey was set up to meet this need, it became apparent that there were problems facing other Government Departments which could only be solved by the method of interviewing samples of the population, and to meet this need the Survey was extended. It now carries out investigations for not only the Ministries of Information and Food, but also for the Board of Trade, the Ministries of Health, Home Security, Works and Buildings, Supply and the War Office.

With the exception of its superintending research officer, none of its staff are Civil servants. This is one of an elaborate series of precautions adopted to make sure that the names of the persons interviewed are not available to the Civil Service. The headquarters staff consists of eight scientific workers, a number of coding tabulators, administrative officers, etc., while the interviewing staff consists of about fifty field-workers. So that this level of scientific work shall be as high as possible, a small panel of scientific consultants has been set up. They are Prof. A. M. Carr-Saunders, Prof. L. T. Hogben, Mr. B. Seebohm-Rowntree, Mr. A. D. K. Owen, Dr. Bradford Hill, and Dr. Aubrey J. Lewis. Every report produced is submitted in interim form to the consultants for critical comment before the final draft is prepared. Further, technical problems in the phrasing of questions, the selection of samples, etc., are submitted, particularly when any difference of opinion arises between a requesting Department and the scientific staff of the Survey. Owing to the speed at which war-time investigations have to be carried out, more detailed consultation is impossible, but the present system has shown that the needs of Government Departments for social survey investigation can be met by a Government-controlled machine without loss of scientific impartiality. Among studies recently undertaken are : the feeding of employed adolescents ; the methods of heating and cooking in working-class households ; salvage habits ; clothes-rationing problems ; food-rationing problems ; and a study of female foundation garments. It will be noted, of course, that this useful Survey is dealing with problems arising out of the War.

Nazism and Science

IN a recent Thinker's Forum pamphlet entitled "The Nazi Attack on International Science" (London : C. A. Watts and Co., Ltd., 6*d*.), Dr. Joseph Needham presents a brief but telling analysis of the nature of Nazism, and describes some of the effects it has produced in science and learning both inside Germany and outside. Society is now passing through an era of change from individualistic capitalistic economics to some form of collectivism, and just as the earlier change from a feudal aristocracy to capitalist democracy was marked by violent upheavals such as the Thirty Years' War and the French Revolution, so Dr. Needham believes that Nazism and Fascism are by-products of the present phase of the evolution of society. The necessary conditions are two powerful groups between which there are relations of mutual fear ; and the racketeer, in this case the Nazi, plays off one against the other. The Nazis have played this part successfully with the German people and also with other nations. Having attained power, the Nazis had to have "a nation of tools". This they achieved by the doctrines of anti-intellectualism, racialism, restriction of science to matters of military value, and the principle of the 'leader'. Incidentally, Dr. Needham points out that the war between China and Japan has its origin in a similar racial-national spirit which has arisen in the latter country.

Turning to biological fallacies exploited by the Nazis, Dr. Needham refers particularly to their misuse of the doctrine of the struggle for existence ; they overlook the distinction between inter- and intra-specific competition, forgetting that the latter has led to the development of unwieldy size, exaggerated fertility and other characteristics which in the past have brought about the extinction of the species concerned. They also make play with the analogy between the social organism and the animal body with its various organs or members. But associations of organisms capable of rational thought cannot be regarded as associations of living cells having only the primitive characters of life. It is a fundamental mistake "to suppose that higher levels of organization can be explained and handled in terms of lower levels". Dr. Needham recapitulates the facts already known about the repression of learning in Germany and the occupied countries, the dismissals of staff and their replacement, if at all, by political figures. One example of the effect of repression on scientific publications quoted by Dr. Needham is worth mention. Three scientific journals in his own field of work were, even before the War, one fifth or less of their former size ; one of these, the *Biochemische Zeitschrift*, decreased from 13 volumes in 1927 to 5 in 1938 and 2 in 1939, although the number of non-German contributors remained roughly the same. Science in Nazi Germany is valued solely in its relation to the needs of war.

British Electrical and Allied Industries Research Association

THE twenty-first annual report (Ref. E.R.A./*T*320) of the British Electrical and Allied Industries Research Association summarizes the work which has been carried out during the year ended September 30, 1941, and lists by titles the various research reports which have been issued during the period. The work is reviewed in seventeen major classifications among which are the highly important ones of dielectrics, cables and overhead lines, electric control apparatus, steam-power plant and condensers, magnetic materials, transformers, surge phenomena and rural electrification. Emphasis is laid upon the work which is still being carried out on circuit making and breaking, surge phenomena, and the properties of insulation, and attention is directed to the consideration now being given, for example, to the storage of electrical energy, the mechanical strength of transformer windings, and the quality improvement of electrical sheet steel. Practical circuit breaker design has been influenced considerably by the Association's investigations. In the insulating materials field, special account is being taken of the latest developments in plastics.

A new section with appropriate sub-committees has been set up to deal with problems of transformer engineering arising especially from war-time and post-war requirements. An exhaustive account has been published of seven years investigation for the Central Electricity Board on surge phenomena, and work has been carried out at the National Physical Laboratory on the surge properties of insulating materials and the surge resistance of tower footings. Researches on conductors, earthing, continuity and on electric control apparatus continue, and the hard gas circuit breaker is receiving special attention. The work of the Association on the application of electricity to agriculture and horticulture continues and is beginning to receive wider recognition in those circles.

The report discloses that the work of the Association is now carried on by no less than 109 technical sections, sub-committees and panels, comprised of experts engaged in industry and in universities and other training institutions. Eighty-three technical reports, relating to a wide variety of subjects, have been issued by the Association during the year, and thirty others were in an advanced stage of preparation at the end of the year. The Association has been recognized as an essential undertaking and a closer liaison has been developed during the year with the Ministry of Supply and, to a lesser degree, with the Fighting Services. The activities of the Information Bureau and Library have been increased by war-time requirements, and work on a complete analytical index to reports of the Association has been carried on during the year. The report is an encouraging survey of the researches which are being undertaken for the electrical industry to meet the needs, not only of war-time requirements, but also of the post-war reconstruction period. It is rightly considered that particular importance should be attached to reconstruction problems, which should receive adequate and timely attention from the point of view of research as new ideas, findings and methods must be absorbed by industry long before research results are needed in commercial enterprises.

Agricultural Meteorology in India

THE annual report of the Agricultural Meteorology Section, India Meteorological Department, for the year 1939–40 covers the last year during which the section was being financed by the Imperial Council of Agricultural Research, the Government of India having taken over the Section from April 1, 1940. The report describes a number of investigations, most of them concerned with the micro-climatology of crops, that is, with the climates experienced within growing crops, as distinct from the more artificial climate of the ordinary meteorological instrument enclosure which is of greater interest for comparisons between the climates of different countries. A number of new instruments have been developed, including several forms of portable but accurate galvanometer for use with thermocouples of copper and constantan for the measurement of temperature in micro-climatology. The recently completed 35-ft. tower at the Central Agricultural Meteorological Observatory at Poona has been found very useful for mounting thermographs, hygrometers and anemometers, for studies of the variations of temperature, humidity and wind with height, which are important in the control of the vertical exchange of heat and moisture between the soil and the overlying air. At Poona, insolation even in January is found to be so strong that the convective layer, with temperature decreasing with height, does not normally disappear during the night, and is generally still to be observed as a layer one or two feet thick at 6 a.m., when temperature in the lower layers is near its minimum. At that time it is generally coldest at a height of one or two feet, with temperature increasing upwards from that level for several hundred feet, the rise amounting already to about 3° C. on reaching the top of the 35-ft. tower. By April the greater insolation is more than counteracted in its tendency to maintain the convective layer by the effect of a higher average nocturnal wind speed, the net result being that the layer has almost disappeared by 6 a.m. The report includes a number of other studies relating to micro-climatology, among which is a table showing the average wind speed in the afternoon at various heights up to 8 ft. in eight different crops, expressed as a percentage of the wind at the same height above open ground. Up to 2 ft., wheat and sugar cane show the highest degree of sheltering, tobacco and suran the least.

Nobel Laureates in the United States

THE philanthropy of Alfred Nobel, the Swedish industrialist, is usually commemorated on December 10 in Stockholm or Oslo with the announcement of the new Nobel Prize winners. In its place a dinner was held in the United States on December 11 at which eleven Nobel laureates were guests of honour. The celebration marked the fortieth anniversary of the first awards. Nobel laureates who were present at the dinner included Dr. Viktor F. Hess, Dr. C. J. Davisson, Prof. Enrico Fermi, Prof. Otto Meyerhof, Dr. Karl Landsteiner, Dr. Irving Langmuir, Prof. H. C. Urey and Prof. Peter J. W. Debye. Dr. Vilhjalmur Stefansson presided.

Medical Research Council: Radiotherapeutic Research Unit

THE Medical Research Council announces that its Radiotherapeutic Research Unit (formerly Radium Beam Therapy Research) has now resumed clinical work in new quarters which have been provided by the London County Council at Hammersmith Hospital. For the present, this work will be confined to the treatment, by radium beam therapy or X-rays, of cases of carcinoma affecting the buccal cavity, tongue, pharynx and larynx. The director, Dr. Constance A. P. Wood, would be glad to have suitable cases referred to her: these should be patients who have had no previous treatment, either surgical or radiological, and preferably not in a very advanced stage of the disease. The physical work under the charge of Mr. L. G. Grimmett, which has meanwhile been continued in temporary quarters at the Imperial College of Science and Technology, has also been transferred to Hammersmith Hospital.

American Chemical Society: New President

DR. PER K. FROLICH, director of the Chemical Division of the Esso Laboratories of the Standard Oil Development Company at Elizabeth, N.J., known for his work in the development of synthetic rubber, has been elected president of the American Chemical Society for 1943. Dr. Frolich took office as president-elect on January 1, when Dr. Harry N. Holmes, head of the Department of Chemistry at Oberlin College, became president, succeeding Prof. William L. Evans, head of the Department of Chemistry at the Ohio State University. In addition to his contributions to the development of synthetic rubber, Dr. Frolich is best known for his work on transformation and chemical utilization of hydrocarbons, high-pressure gas reactions, catalysis and applied colloid chemistry. On September 9, 1940, he and his research associates read the first technical report on the discovery of butyl rubber, made from petroleum.

Dr. Frolich was born in Christiansand, Norway, in 1899, and graduated from the Norwegian Institute of Technology in 1921. He received the degree of master of science from the Massachusetts Institute of Technology in 1923, and the degree of doctor of science from the same institution in 1925. He was assistant chemist at the Norwegian Institute of Technology during 1919–1921, instructor at Christiansand Business College during 1921–1922, and American-Scandinavian Foundation fellow at the Massachusetts Institute of Technology during 1922–1923. He served as assistant in the Massachusetts Institute of Technology Research Laboratory of Applied Chemistry during 1925–1927. He became assistant director of the Laboratory in 1927 and was advanced to associate professor in 1929, the year he joined the staff of the Standard Oil Development Company. He was awarded the Grasselli Medal in 1930 for outstanding achievement in chemistry, particularly in the field of high-pressure reaction of gases.

Centenary of Flammarion

CAMILLE FLAMMARION, the French astronomer whose books found readers in all parts of the globe, was born on February 25, 1842, at the small town of Montigny-le-Roi, in Haute-Marne. The son of a shopkeeper, he was educated at a church school and then began work in an engraver's office. His merits being brought to the notice of Leverrier, at the age of sixteen he was given a place in the Paris Observatory, where he stayed four years. At the age of twenty he published his first book, "The Plurality of Inhabited Worlds", the forerunner of his "The Marvels of the Heavens", "Popular Astronomy", "The Planet Mars", "Astronomy for Amateurs" and many others. His "Popular Astronomy" when first published in French in 1879 was awarded the Montyon Prize of the Paris Academy of Sciences and was selected for use in the French public libraries. Through an admirer of his writings, Flammarion, in 1883, came into possession of a small château and park at Juvisy-sur-Orge and he built an observatory there. The previous year he had founded the review, *L'Astronomie*, and five years after that, in 1887, he started the Société Astronomique de France. His death took place at Juvisv, June 4, 1925, when he had reached the age of eighty-four.

University of Sheffield

THE University of Sheffield has received a bequest of £1,200 by the late Mr. L. N. Ledingham to found a bursary fund for students in the Department of Metallurgy, to be called "The Ledingham Bursary Fund".

The Council decided that because of the close association of the Department of Pharmacology with clinical teaching and because the professor of pharmacology is responsible for the teaching of therapeutics, the Department of Pharmacology should in future be given the title of Department of Pharmacology and Therapeutics, and that the professor of pharmacology should be given the title of professor of pharmacology and therapeutics.

Announcements

DR. R. L. WATERFIELD has been awarded the Jackson-Gwilt Medal and Gift of the Royal Astronomical Society "for his general contributions to astronomy, and in particular for his photographic work on eclipses and comets and his visual observations of planets". The Medal will be presented at the annual general meeting to be held on April 10.

THE King has approved the following awards of the Polar Medal in silver for good services with the Oxford University Arctic Expedition to North East Land in 1935 and 1936: Lieut. A. R. Glen; Instr. Lieut. R. Moss; A/Major N. A. C. Croft; Major A. S. T. Godfrey; Capt. A. B. Whatman; R. A. Hamilton, D. B. Keith, A. Dunlop-Mackenzie, J. W. Wright.

THE Edison Medal for 1941 has been awarded by the American Institute of Electrical Engineers to Prof. J. B. Whitehead, director of the school of engineering of the Johns Hopkins University, "for his contributions to the field of electrical engineering, his pioneering and development in the field of dielectric research, and his achievements in the advancement of engineering education".

THE Committee of the Athenæum has elected the following gentlemen, under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, or the arts, or for their public services: Air Chief Marshal Sir Wilfrid Rhodes Freeman, Vice-Chief of the Air Staff; Prof. E. H. Minns, emeritus professor of archæology, University of Cambridge; Prof. P. H. Winfield, Rouse Ball professor of English law, University of Cambridge.

DR. H. SPENCER JONES, Astronomer Royal, will deliver the Symons Memorial Lecture of the Royal Meteorological Society on March 18. He will speak on "The Atmosphere of the Planets".

The following appointments in the Colonial Service have recently been made: Mr. J. C. Alley, veterinary officer, Nigeria; Captain L. Nicholls (conservator of forests), deputy chief conservator of forests, Nigeria.

WE have received a copy of the 1941 edition of the Official Directory of the British Chemical Plant Manufacturers' Association, containing a directory of members, a classified list of products and services, a list of proprietary and trade names and marks, and other information. A copy of this Directory will be issued gratis to inquirers interested in the purchase of British chemical plant on application to the Association, 166 Piccadilly, London, W.1.

ERRATUM. In the article "Feeding Post-War Europe", by Dr. Geoffrey Bourne, NATURE, February 14, p. 182, the amount of vitamin C required by Great Britain should read "700 tons" and not "30 tons" as printed.

WE regret that it has not yet been possible to issue the Index to vol. 148 of NATURE. An announcement will be made as soon as the date of publication is fixed.

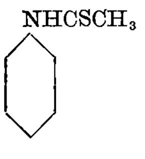
Hydrogen Bonds Involving the Sulphur Atom

The view is very generally expressed[1] that sulphur does not take part in hydrogen-bond formation. This conclusion is based mainly on the normal physical properties of hydrogen sulphide, as compared with water, and on the absence of molecular association in thioalcohols and thiophenols. Such evidence is obviously only valid against the S-H-S bond.

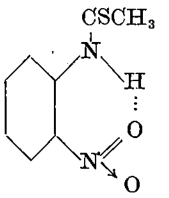
On the contrary, there are various indications that the sulphur atom can form hydrogen bonds of the type S-H-O and S-H-N possessing considerable stability. For example, quinhydrone-like complexes between quinones and thiophenols or mercaptans have long been known; their existence is probably due to S-H-O bonds. Again, the tautomerism of the thio-acids, $R.COSH \rightleftharpoons R.CSOH$, is probably attributable to their associated (hydrogen bond) structure. Contemporary American workers have recently attributed the anomalous behaviour of mercaptans in certain donor solvents in regard to heats of mixing[2], and infra-red absorption[3], to the formation of weak S-H-N and S-H-O bonds.

Recent work[4] from this laboratory has indicated that a factor which contributes more than any other to hydrogen-bond stability is the condition that the hydrogen atom constituting the bond should be tautomeric. We have, therefore, sought evidence of hydrogen-bond formation in the thioamides and the thioanilides, the tautomeric behaviour of which is formally represented by the equilibrium $R.CSNHR' \rightleftharpoons R.C(SH):NR'$. Cryoscopic measurement of molecular weight of a large number of thioamides in naphthalene solution has shown that those which possess an unsubstituted imino-hydrogen atom (as in $R.CSNH_2$ and $R.CSNHR'$) exhibit marked molecular association, whereas those in which both imino-hydrogen atoms have been replaced (for example, $R.CSNRR'$) are invariably unimolecular. It would appear, then, that the association of the former type is due to intermolecular S-H-N bonds.

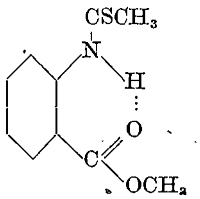
Further evidence of the hydrogen-bond structure of the thioamides is provided by the behaviour of nuclear-substituted derivatives of thioacetanilide (I). We find that the considerable molecular association shown by this compound[5] is completely checked by the substitution of suitable *o*-substituents capable of chelating with the anilido-hydrogen atom. Evidently, the hydrogen atom thus engaged is incapable of further union with the sulphur atom of a second molecule. Thus, *o*-nitro- (II) and *o*-carbmethoxy-thioacetanilide (III) are substantially unimolecular.



(I)



(II)



(III)

A parallel investigation of the molecular condition of the thioacids has confirmed that they also are associated (originally observed in the single case of thioacetic acid by Auwers[5]), whereas their esters ($R.COSR'$) are not. Evidently the association of the thioacids is due to intermolecular S-H-O bonds.

A more complete account of this work will be published elsewhere.

Quantum Efficiency of Photosynthesis

It is generally accepted that about four energy quanta of red light ($\lambda = 660\ \mu\mu$) are needed to promote the assimilation of one molecule of carbon dioxide. This conclusion is based in the main on the measurements of Warburg and Negelein[1], who determined the ratio W/E, that is, the volume of carbon dioxide assimilated by Chlorella during the absorption of one calorie of light energy. They designated this ratio by φ and, since it is well known that φ increases with decrease in light intensity, the value φ_0 found with the minimum intensity was adopted.

As the mean of nine measurements it was found that 116·8 c.mm. of carbon dioxide were assimilated during the absorption of one calorie of red light energy. It follows from this that 191,781 calories would be absorbed during the assimilation of one gram mole of carbon dioxide and, since the value of $Nh\nu$ at $\lambda = 660\ \mu\mu$ is 43,112 calories, that 4·45 energy quanta were absorbed for each molecule of carbon dioxide assimilated. In a similar series of measurements with blue light ($\lambda = 436\ \mu\mu$) it was found 5·1 energy quanta were absorbed for each molecule of carbon dioxide assimilated.

Now these and any similar determinations of the quantum efficiency of photosynthesis are based on the assumption that the whole of the light energy absorbed is utilized in promoting the assimilation of carbon dioxide. Expressed in other words, this assumption means that the absorption of light energy by Chlorella is entirely caused by the photo-assimilation which takes place. If this were correct, a suspension of Chlorella in which photo-assimilation has been inhibited by hydrogen cyanide would not absorb red or blue light and hence would be almost colourless.

Furthermore, Warburg[2] proved that, when the light intensity and temperature are maintained constant, the number of molecules of carbon dioxide assimilated in unit time by Chlorella increases at first very rapidly and then more slowly as the external concentration of carbon dioxide is increased from 1×10^{-6} to 90×10^{-6} gram mole per litre. On the assumption made by Warburg and Negelein, this indicates that the number of energy quanta needed to promote the assimilation of one molecule of carbon dioxide decreases with increase in the external concentration of carbon dioxide.

Then again it is well known that the leaves of plants exhibit fluorescence during photo-assimilation and Kautsky and Hirsch[3] proved that the intensity of this fluorescence is much less with strongly assimilating leaves than under normal conditions. This radiation of light energy during photo-assimilation proves that the whole of the light energy absorbed is not utilized in promoting assimilation.

It thus becomes manifest that the assumption that the whole of the light energy absorbed is utilized in promoting photo-assimilation cannot be justified. Warburg and Negelein's calculations of the quantum efficiency would, therefore, appear to be invalid.

Waves and Tidal Streams

IT has been shown[1] that the steepness of secondary waves riding on primary ones ranges from $s(1-\pi S)^{-2}$ to $s(1+\pi S)^{-2}$, at crest and trough of primary, S and s being primary and secondary steepness. The special case in which the tidal wave is the primary, and the larger wind-formed waves are the secondaries, is of some interest. As S is then almost nil, s does not vary. This means that the steepness of wind-formed waves is unaffected by the mere turn or making of the tidal stream. So some further explanation must be sought for the great change in the state of the sea when the stream turns to the weather, a change too great to be accounted for by the increase in speed of wind over water, and one which ordinarily takes place even after the wind has dropped, as will be assumed here.

Change in direction or strength of stream will not change the steepness of the waves if they are travelling through an area of uniform tidal strength—uniform maximum strength. It is different when the (maximum) strength varies as between one position and another. Then maintenance of the sequence of the waves constituting the swell involves the crests opening out or closing up according to the change in stream, the closing up of sailing vessels as they run into a calm patch, or of road traffic which has to climb a steep hill, being analogous examples. The reduction in length when waves meet a foul stream of greater strength entails reduction in their speed, and in the speed of their energy through the water, with greater percentage reduction in the speed of the energy over the ground. Then continuity of the supply causes the energy to crowd up, and the greater number of units of energy squeezed into each square foot of water surface entails increase in wave height. Thus wave-length is reduced, and wave-height increased, and the sea steepens.

It will suffice to take the case in which waves run from a deep slack-water area into one in which the depth is D and speed of stream C, for the final result will be the same whether they pass directly from depth D_1 and stream C_1 into depth D_2 and stream C_2, or do so through intermediate deep slack water. Let L_0, T_g, V_0, G_0 be length, period and speeds of waves and energy in deep slack water, and L, V, G_w, G_g be length, wave speed through water, and speeds of energy through water and over ground, where the depth is D and the stream has speed C, C being negative when weather going or foul. T_g will also apply to the second area, if observed from the shore. Owing to continuity of sequence :

$$T_g = \frac{L_0}{V_0} = \frac{L}{V+C}.$$

It follows that

$$\frac{V}{V_0} = \tfrac{1}{2}\tanh\frac{2\pi D}{L}\left\{1 \pm \sqrt{1 + \frac{4C}{V_0}\coth\frac{2\pi D}{L}}\right\};$$

or, for deep water,

$$\frac{V}{V_0} = \tfrac{1}{2}\left\{1 \pm \sqrt{1 + \frac{4C}{V_0}}\right\}$$

Where $C = -\tfrac{1}{4}V_0$ in deep water, $G_g = 0$, and the waves must break, however small their initial steepness. This leads to the rather unexpected result that waves with slack water lengths of 100 and 400 ft. cannot stem streams stronger than 3½ and 6¾ knots. With appreciable initial steepness they will break at earlier stages, but may survive after some of their energy has been dissipated into heat. Thus in a tide race, or on a bar, there may be more or less standing lines of breakers, even without sudden change in depth. To leeward of the position where $C = -\tfrac{1}{4}V_0$, the sea will be calm.

When D/L is small, the plus sign only operates until $C = -\tfrac{1}{4}V_0$. Then the minus sign comes into play, and holds good until $G_g = 0$. But its reign will be a short one, for analysis shows that unless D is less than $L_0 \div 20$, the minus sign only starts to function when C is within 5 per cent of the strength necessary to reduce G_g to zero.

As $G_w = V - L\frac{dV}{dL}$, $L\frac{dC}{dL} = G_g$: and so, when G_g has become small, the waves only retain a small margin of stability, and the sea will be confused.

For present purposes, stream athwart the direction of wave travel may be ignored, and the water regarded as slack. So onshore waves may be taken as passing from slack water into stream, fair or foul, as they enter an estuary. Those which enter late on the ebb will steepen, and in so far as the estuary is of uniform tidal strength, their steepness will be unaffected by the turn of the stream. But later waves, entering on the early flood, will lengthen, so that their energy will travel faster through the water, and tend to catch up that of the earlier batch. This may account for what would otherwise seem a rather astonishing statement on the part of some Bristol Channel pilots—that the worst seas off the Foreland occur towards the end of the flood. The Bristol Channel is almost long enough for overtaking to take place, so that the two lots of energy tend to become superimposed.

When the earlier batch of energy, intensified by entrance on the ebb, passes a bay in the shore of the estuary after the flood has made, the drainage from its main stream due to its spreading out laterally into the bay will be rapidly made good, owing to its increased speed over the ground. Thus the supply is maintained, and there will be a heavy roll in the bay during the flood, a common occurrence.

Lastly, as the length of swell is unaffected by the mere turn of the stream, observation of period, made from the shore of an estuary, may not necessarily give an accurate indication of wave-length in the open.

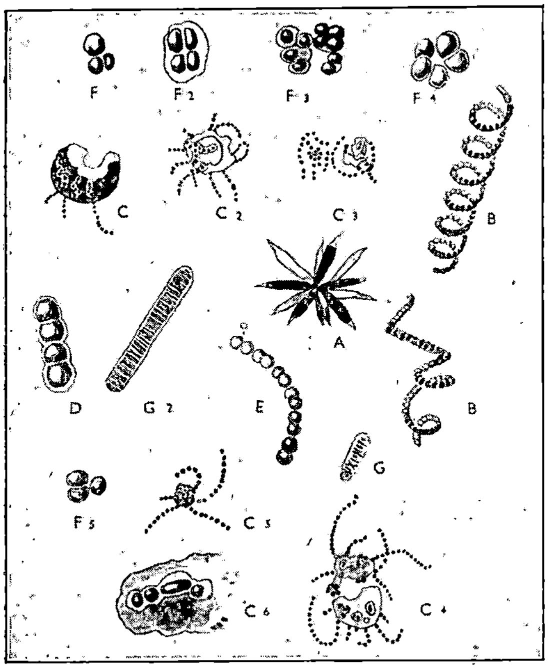
Normal Rumen Microflora and Microfauna of Cattle

The elucidation of the factors concerned in the digestive assimilation by cattle of starch, cellulose, and also of protein substitutes, necessitates an accurate knowledge of the functional activities of the rumen micro-organisms. On this subject very conflicting opinions have been advanced[1,2,3] based in many cases upon the results of inoculation of rumen-contents into artificial media. The value of these results, moreover, must always remain uncertain[4,2] until the characteristics of the normal rumen microflora and microfauna have been independently determined by direct microscopical observation. Appropriate methods have been applied by me to the investigation of the gastro-intestinal contents of various herbivora[4,5,6,7,8].



Iodophile microflora of cattle.

A, rosette association of unidentified organisms; *B*, giant spirillum; *C*–*C*$_5$, stages in disintegration of starch grains by coccoids; *C*$_6$, surface of grain showing lacunæ surrounding coccoids; *D*, coccoid chains (giant form); *E*, coccoid chains (normal type); *F*–*F*$_5$, sarcina packets; *G*, *G*$_2$, *Oscillospira guillermondi*.

With the assistance of a grant from Imperial Chemical Industries, Ltd., these studies were extended in order to afford a microbiological control to *in vitro* incubations of rumen contents in progress at the Hannah Dairy Research Institute[9]. Observations were made upon local (Guildford) slaughter-house material as well as upon fistula samples submitted by the Institute. Fresh and formalized material was examined. The very numerous samples investigated made it possible to construct a representative picture of the normal rumen microflora and microfauna. This always includes:

(*a*) Protozoa of the families Ophryoscolecidæ and Isotrichidæ. These have been described and monographed by numerous investigators[10,11].

(*b*) An iodophile microflora, that is, an association of taxonomically diverse species exhibiting, in consequence of the presence in them of 'bacterial starch' or granulose, the common characteristic of giving a blue reaction with iodine. Such organisms have hitherto received scant attention from the majority of investigators, though they are found in all domestic Herbivora[12]. At least five species easily distinguished by their large size ('giant' forms) and characteristic morphology were invariably encountered, namely:

(1) *Oscillospira guillermondi*, Chaton and Perard[13] (Oscillaria caviæ, Simons[14]). A colourless spore-forming oscillarian (5–20 × 3–4 μ).

(2) *A giant spirillum* (15–40 × 1–2 μ) divided internally by transverse septa into spherical or ovoid compartments.

(3) *Large Sarcina packets* (1·5–3 μ).

(4) *An unidentified navicular organism* (bacterium) forming rosette-shaped associations of 5–30 units (4–8 × 0·9–1·5 μ).

(5) *Coccoid chains* of 2–8 units (*a*) (4–10 × 1·5–2 μ). (*b*) (*Smaller variant* 15 × 1·2–1·5 μ).

By the use of the polarizing microscope and histochemical methods[1,13], it was demonstrated that certain iodophile micro-organisms play a determinant role in the decomposition both of starch and cellulose. These results confirm those established by me for other Herbivora[2,4].

The functional activities of the rumen micro-organisms can be still further elucidated by *in vitro* incubations of rumen contents. In such experiments the maintenance of the iodophile microflora and protozoan microfauna clearly establishes the preservation of normality over the period of incubation. During this period, therefore, the results of biochemical and micro-biological analysis may reasonably be assumed to give a true representation of processes occurring in the living animal. By the use of counting methods the influence of chemical and physical factors upon the growth-rate of the iodophile micro-organisms could be ascertained. Thus a qualitative and quantitative control of the conditions established *in vitro* was secured.

Afferent Innervation of Mammalian Abdominal Viscera

THE afferent nervous pathways from abdominal viscera have been studied by McSwiney and his co-workers by means of the changes in pupil diameter induced by stimuli such as weak faradic shocks applied to the central end of the cut splanchnic nerve (Bain *et al.*[1]), or to the central end of the cut abdominal vagus nerve (Harper *et al.*[2]). Investigations, by oscillographic methods, of the afferent nervous activity in the frog's viscera have been carried out by Tower[3], and later confirmed by Burns[4]. It was shown that the gut and mesentery gave rise to fast nerve impulses in the sympathetic rami in response to light touch. These impulses are not dissimilar to those in cutaneous sensory nerves in response to light touch on the frog's skin. On examining the afferent nervous mechanism in visceral nerves of the cat and rabbit, it has now been shown that a somewhat similar mechanism sensitive to light touch is present. Thus in response to light touch on the gut or the mesentery, trains of impulses of a fast type can be shown to ascend in the small nerve trunks which run, in company with blood vessels, across the mesentery from its intestinal attachment towards the mesenteric root. The exact distribution of this tactile sensibility and the function of the cat's mesenteric Paccinian corpuscles are being investigated.

Biology and War

IN these days when both comfort and efficiency are so dependent upon science and its applications, it is surely astonishing that so little weight is attached to the teachings of biological—apart from medical and agricultural—science in relation to problems which in these days have urgent importance.

An impressive example is afforded by the continued misuse of paint or pigment in relation to camouflage although the main principles of this were worked out more than a quarter of a century ago. Another is seen in the development of aircraft with refusal to grasp the fact that Nature had provided in the bodies of rapidly swimming fish a ready-made demonstration of the streamlined form most effective for rapid movement, whether through a denser medium such as water or a more tenuous one such as air. It is only now, after much needless expenditure of time and money, that the fuselage of fighter aircraft is seen to attain the correct form indicated by Nature.

Still another is concerned with the varying power of 'light' of different wave-lengths, as regards, on one hand, visibility by the human eye and, on the other, power of penetrating the atmosphere. A walk along a straight road on a hazy winter evening is enough to show by the reddening of the lamps with increasing distance the greater penetrating power of rays towards the red end of the spectrum. A walk by day when the sky is clear but the ground enveloped in thick haze shows a complete absence of the sharp shadows of sunlight; and yet the photographer armed with films sensitive to infra-red rays sees these shadows sharply depicted in his photographs, the infra-red rays finding their way past the water particles suspended in the atmosphere until these become big enough to form wet fog or rain. Yet no steps are taken to compel all ships of considerable size to be equipped with the necessary apparatus—photographic or fluorescent—to see through haze dense enough to conceal dangers to navigation though fine enough in the size of its water particles to allow the passage of the infra-red rays.

Blindness to such simple examples is necessarily accompanied by blindness to more elusive teachings of biology. Perhaps the most striking feature in the evolution of animal organisms is their advancement in size from small microbes to the relatively large creatures familiar in the animal world of to-day. This onward progress is a normal feature of evolution. It brings with it increased efficiency, increased power, increased speed of movement. But it also brings with it the seeds of decay and death. The geological record of evolution is littered with the remains of great powerful creatures which have become extinct while their smaller, feebler contemporaries have survived. The increase in size has in fact been attainable only by a corresponding increase in complexity of organization, involving the development of an ever greater multiplicity of parts, an ever greater sensitiveness to impressions from without, an ever greater centralization of control both over normal activities and over the appropriate reactions to emergencies. All this brings with it serious danger: vital processes are apt to become clogged and slowed down; destruction may come to the whole through the failure of some small part.

Blindness to such biological facts finds expression in many of our troubles of to-day. The air is full of complaints regarding the slowness of Government departments to act or to react—slowness which at times may have disastrous consequences. It is unfair in such cases to concentrate all the blame upon particular officials. It should rather be realized that many departmental shortcomings are inevitable results of their growth in size; and the only sure way to get rid of them is to diminish the potency of the size factor by a reversal of the normal evolutionary development. In some cases this can be effected by the resolution of the overgrown department into a number of more or less independent smaller ones. In others where this is not practicable, much can be done by the free delegation of authority by the central government to local bodies familiar with local conditions and free to take action on their own responsibility. The obvious dislike of the central departments to delegate any of their authority, to give up any of their powers of control, seems sometimes to imply a cynical disbelief in the reasonableness, or indeed the honesty, of the average citizen—a view which if it exists is most undoubtedly wrong.

RESEARCH ITEMS

Early Man in New Mexico

An interesting excavation has been undertaken by F. C. Hibben, of the University of New Mexico, at Sandia and other cave sites in the Sandia-Manzano region of New Mexico. A stratigraphical sequence of deposits was obtained, there having been six levels in all, three of which contained archæological remains separated by sterile layers (Smithsonian Miscellaneous Collections, 99, No. 23). The uppermost level yielded pottery of early Spanish or immediately pre-Spanish date, the second one produced a Folsom industry, while from the lowest archæological bed there was unearthed a new pre-Folsom industry to which has been given the name of the site—Sandia. This industry, judging from the descriptions and photographs, would seem to be related to that of the middle, Folsom, level, but must be considered more primitive. Its typical tool is a sort of shouldered laurel leaf. At the bottom of this Sandia level the standard of flaking was not too good, very different indeed from the beautiful technique used by the makers of the true Folsom points. "Basal thinning" and "facial channels" are absent; the edges of the bases are smooth. The Sandia points from the upper part of the level, however, are far better made, being elongated with parallel sides and straight or somewhat indented butts. As before, the points are shouldered, doubtless for hafting purposes. A few scrapers were found, but the Sandia level as a whole was not rich in types. Such a clearly stratified pre-Folsom industry as this is obviously a matter of great interest. In an appendix to Hibben's paper, Kirk Bryan of Harvard University has attempted to demonstrate a high antiquity for the Folsom and Sandia levels at this site. He bases his theory on a study of the deposits themselves, which leads him to the conclusion that the Folsom layer is to be equated with our Pomeranian (late quaternary) glacial stage (= Mankato continental ice of North America), while the Sandia level is, of course, even older. This problem of the antiquity of man in the Americas is always cropping up, and it will be interesting to see whether Kirk Bryan carries his colleagues with him in assigning such a great age to these industries.

Elasticity of Bovine Cervical Mucus

An interesting adaptation of the measurement of a physical property to the study of a biological process is given by Scott Blair and others (*Biochem. J.*, 35, 1039; 1941). Determination of nitrogen and solid content, viscosity and flow elasticity have been made on bovine cervical mucus during the œstrous cycle. Flow elasticity shows a marked maximum at œstrus, and a simple apparatus, the 'œstroscope', for the measurement in the cowshed is described. It is believed that the œstroscope technique should be of practical value to stock breeders, especially for prediction of œstrus in cases where it is liable to be missed and for its diagnosis in cases where ovulation is unaccompanied by external signs of heat (see also Nature, 147, 453; 1941).

Lecithinase Activity of *Cl. welchii* Toxins

Knowledge of the chemical nature of the specific toxins from toxic culture filtrates would be advantageous in preparing antitoxic sera and in studying the mode of action of the toxins on the cell. Because of the importance of *Cl. welchii* in war-wound infections, M. G. Macfarlane and B. C. J. G. Knight (*Biochem. J.*, 35, 884; 1941) decided to investigate the enzymic activity of toxic culture filtrates of this organism. It has been known that the activity of the toxin in producing an opalescence in human serum or egg yolk is a measure of α-toxin content. The authors now show that the specific α-toxin, the lethal hæmolytic and necrotic factor, is probably identical with a lecithinase (optimum *p*H 7·0–7·6) activated by Ca^{++}, which decomposes lecithin into phosphocholine and a diglyceride. It is probable that this lecithinase would confer hæmolytic and necrotic powers on the toxin, since it would have a disintegrating effect on any cell membrane or intracellular lipoprotein complex the integrity of which depended on the presence of lecithin. The anti-lecithinase activity of *Cl. welchii* (type *A*) antitoxic sera runs parallel with the animal protection titre and is a fair measure of the α-antitoxin.

Problems of Bee Keeping

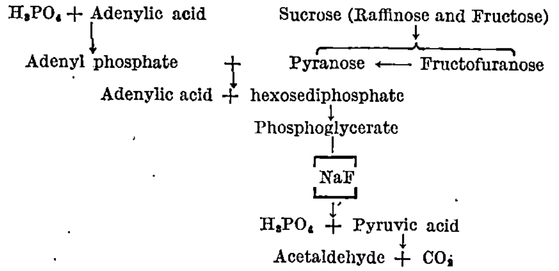
It is learned from the *Bee World* of January, 1942, that some important advances in knowledge of bee diseases have emanated from the Liebefeld Research Institute. It appears that Hans Schneider has found that a form of the mite Acarapis, which frequents the wings and first abdominal segment, is distinct from those previously known. The provisional name of *A. vagans* has been given (*Mitt. Schw. Entom. Ges.*, 18, 6; 1941). This mite is stated to occur only in quantity in stocks badly infected with Nosema. Prof. R. Burri, until 1937 director of the Institute named above, has made a notable advance in knowledge regarding European foul brood. He claims that the organism concerned, namely, *Bacillus pluton*, has been cultivated for the first time in an artificial medium. This discovery if substantiated is one of great value since there has always been room for doubt whether *B. pluton* is the actual causative agent of European foul brood disease because it could never be cultivated outside the bee larva. So far no particulars have been published regarding the nature of the culture medium employed. A third item referred to in the *Bee World* concerns the Frow remedy for acarine disease. It appears that V. Peterka and J. Svoboda have found that nitrobenzene is the ingredient in the Frow treatment that is lethal to the mites concerned. They also find that safrol oil does not kill the mites and is the substance responsible for injuring the bees. They therefore substituted methyl salicylate for safrol oil and found that the treatment thus modified is preferable to the original remedy.

Inheritance in the Grasshopper

M. Creighton and W. R. B. Robertson (*J. Hered.*, 32, 339) have studied the inheritance of several colour patterns of *Chorthippus longicornis* of Iowa which may correspond with *C. parallelus* of Britain. Their results show that there is a multiple allelomorph series which controls colour on the sides and back. The most commonly found colour form—'plus' type—is the most recessive form. Interesting comparisons are made between the life-histories of *C. longicornis* in Iowa and *C. parallelus* as studied by Sansome and La Cour (*J. Gen.*, 30, 415; 1935). The colour forms are different, while the number of eggs per pod, the time of development of the insect and the development of elytra are dissimilar.

Respiration in Barley

In two further contributions by James and his co-workers to our knowledge of the respiratory system in barley (James and Bunting, *New Phyt.*, 40, 268; 1941; Bunting and James, *New Phyt.*, 40, 262; 1941) the carboxylase activity of barley powders and expressed saps is further examined and its presence confirmed. From the fact that a mixture of the sap and the powder obtained from the residue after sap expression is greater than the sum of their separate activities it is further concluded that the carboxylase system includes an insoluble apoenzyme and a soluble coenzyme. A typical clear barley sap gave a positive fluorescence test for cocarboxylase and it is estimated that 100 gm. of barley tissue contains about 30 γ (as diphosphothiamine) of this substance. In the second paper, respiration in barley is shown to follow much the same course as in yeast. Adenylic acid added to barley saps containing sugar and free phosphate give an increased CO_2 production as compared with untreated controls. The addition of hexosediphosphate and of phosphoglycerate to the digests increases the carbon dioxide output to about the same extent, and the effect of the former is completely inhibited by *M*/40 sodium fluoride. Since the enzymatic conversion of phosphoglycerate to pyruvic acid is exceptionally sensitive to this poison, it is concluded that phosphoglycerate follows hexosephosphate in the chain of respiratory reactions. From this and previous work, respiration in barley is represented along the following expanded scheme:



H_3PO_4 + Adenylic acid
Adenyl phosphate
Adenylic acid + hexosediphosphate
Sucrose (Raffinose and Fructose)
Pyranose ⟵ Fructofuranose
Phosphoglycerate
NaF
H_3PO_4 + Pyruvic acid
Acetaldehyde + CO_2

Kalsilite-bearing Volcanic Rocks in Uganda

At the Mineralogical Society on January 22, A. Holmes described a suite of volcanic rocks from south-west Uganda containing the new mineral kalsilite, a hitherto unrecognized polymorph of $KAlSiO_4$. The leading volcanic types of the Bunyaruguru field are distinguished by the following pairs of the four critical minerals: augite, melilite, leucite and kalsilite.

Ugandite	=	Augite + leucite	With abundant olivine, perovskite and black ore ± glass.
Mafurite	=	Augite + kalsilite	
Katungite	=	Melilite + leucite or leucitic glass	
Kalsilite-katungite	=	Melilite + kalsilite	

For the new rock-type characterized by the association augite-kalsilite the name mafurite is proposed. A heteromorphic variety with abundant biotite is distinguished as biotite-mafurite. Varieties transitional to ugandite are described as leucite-mafurite and kalsilite-ugandite. Melilite-mafurite, transitional to katungite, also occurs. Six new chemical analyses are presented. F. A. Bannister and M. H. Hey have investigated the new mineral by X-ray and microchemical methods respectively. The grains of kalsilite yield a hexagonal Laue pattern which is much simpler than those of nepheline and kaliophilite. The refractive indexes of kalsilite are $\omega = 1{\cdot}542$; $1{\cdot}537$; and it is thus not possible to distinguish kalsilite from nepheline in thin section.

Environmental Factor in Corrosion

According to V. J. Albano (*Bell Lab. Rec.*, 20, No. 3, Nov. 1941) corrosion results from the natural tendency of ordinary metals to revert to stability by combination with the surrounding elements, variation in the chemical properties of which, however, may be such that a metal which is resistant to corrosion in one way becomes attacked quickly in another. In Nature, sufficient traces of moisture and dissolved chemicals are usually present to render the environment active, but under certain conditions protective films form on many metals. Film formation requires an environmental substance that reacts with the metal to form an insoluble, impervious and adherent surface compound. The presence of corrosive substances militates against the formation of such a film. Distilled water lacking film-forming substances corrodes lead very easily, whereas city tap-water covers the lead with an inert and invisible protective film. Environment also governs galvanic corrosion between dissimilar metals, corrosion being accelerated by electrochemical action, seriously so in industrial and marine atmospheres, in soils and in waters. The more direct way to mitigate corrosion is to remove the corrosive constituents in the environment. The removal of dust and sulphur gases from air and the addition of film-forming ions, such as silicates, chromates and phosphates to water, or the removal of activating materials like chlorides, nitrates, and dissolved oxygen are all aids to the mitigation of corrosion. The indiscriminate selection of a metal for service in a specific environment based on its corrosion behaviour elsewhere is both unsatisfactory and uneconomical.

Great Sunspot of September 1941

In the December issue of *Observatory* (64, 161; 1941) H. W. Newton describes the sunspot group which crossed the sun's disk between September 10 and 23, 1941. At maximum, on September 18, the group had an area of about 2,500 millionths of the hemisphere, which ranks it among the 'great' spots. A short-wave radio fade-out beginning at 0830 U.T. on September 17 was evidently associated with a brilliant chromospheric eruption first observed, close to the leading spot, at 0838, and with a characteristic kick on the Abinger magnetic traces at 0821. About 20 hours later an intense magnetic storm began, the major disturbances lasting for more than 24 hours. The total ranges in the magnetic elements during the period were 2° 3′ in declination, 1,252 γ in horizontal intensity, and 1,116 γ in vertical intensity. This range in *V* is bigger than that produced by any other magnetic storm of the present solar cycle. Auroral displays in unusually low latitudes were observed on the morning of September 18 and the evenings of September 18 and 19. The sequence of events here is similar to that of the magnetic storms of March 1 and July 14, 1941, namely, a brilliant chromospheric eruption, accompanied by a synchronous radio fade-out and a small magnetic disturbance, is followed after a day or so by a great magnetic storm and associated auroræ. The eruption is usually associated with a sunspot, though not necessarily with a large one, hence the looseness of the correlation of magnetic storms with great spots. The information accumulated during and since the last sunspot maximum points to the significance of chromospheric eruptions in causing not only the radio fade-outs which occur simultaneously, but also the magnetic storms which follow after a time lag of about 20 hours.

EVOLUTION IN THE PETROLEUM INDUSTRY

IN a paper on the above subject read before the Royal Society of Arts on January 21, Mr. James Kewley did not restrict the term 'evolution' to its purely biological sense of adaptation of species of organisms to changing conditions of environment. Rather he gave to it an added significance and power to embrace not only spontaneous changes, but equally predetermined policies designed by man to meet, or even anticipate, commercial and economic demands. Thereafter he proceeded to determine the measure of success achieved within the industry by citation of facts which by their very baldness proclaim the power of such man-made evolution.

In 1895 the deepest well drilled was 1,200 ft. Then came the cry for greater production of crude oil. To meet this, deeper and deeper wells were drilled until in 1940 the record was held by one sunk to a depth of 15,000 ft., or 2·8 miles. In 1859 the demand was for a reliable and cheap illuminant to replace the vegetable oils then in use. Kerosine fulfilled the demand and remained the chief product of petroleum for nearly forty years.

The next landmark in evolution of the petroleum industry was the incidence of the internal combustion engine, which presented the twofold problem of adequate supply of motor spirit and economic utilization of other crude oil products. Statistics show that in 1915 there were 15·8 tons of crude oil available per automobile registered, and in 1935 only 4·9. Nevertheless the demand for motor spirit was met by increasing its volatility and at the same time the yield of this product from the raw material. Hydrocarbons available in the natural gas from the casing heads of wells and in the gases or uncondensed vapours from distillation plants, for example, pentane and butane, were incorporated in the motor spirit fraction, thus increasing its volatility. Increase in yield by this method, however, was small compared with the impetus given to the industry by development of the cracking process, which proved to be a highly flexible technique both from the point of view of control of yields and character of products obtained. In fact, largely owing to the influence of the cracking process the yield of motor spirit from crude oils has been increased fourfold. In 1910 a yield of 13 per cent was obtained, while in 1940 the estimated figure was 55 per cent.

At this stage parallel evolution in the motor engine industry, involving higher compression ratios, created a demand for motor spirits of higher anti-knock value. That the petroleum industry met this demand is evinced by figures relating to the octane numbers of motor spirits in the United States. In 1931 the anti-knock value expressed in terms of octane-number and related to a standard C.F.R. engine was 58; in 1933 it was 67; and in 1940, 73. It so happened that crude oils produced from fields of younger geological age than those first discovered yielded motor spirits of higher octane number and also that cracking processes produced spirits of better anti-knock value, but whether this had been the case or not, evolution in the petroleum industry would not have been seriously retarded. Large-scale development of dopes, particularly tetra-ethyl lead, would have met the contingency.

Having solved the problem of production of high-quality motor spirit, refiners were faced with the difficulty of commercial utilization of the other components of crude oils. Consumers had to be convinced of the practicability of using fuel oil as an alternative to gas, which was in fact much easier to handle. Persistence was rewarded and when the Diesel engine came upon the scene suitable fuels were already available.

Study of figures for sales of Diesel engines (expressed in horse-power) in the United States indicate how great was the demand for this type of fuel:

1915	... ...	86,000
1925	... ...	536,000
1935	... ...	1,200,000
1939	... ...	2,726,000

The so-called space-heater for domestic purposes created a demand for a distillate intermediate in character between kerosene and gas-oil. The use of asphaltic bitumens for road-making, waterproofing, impregnating and a variety of other purposes became an established fact, and methods of blowing or oxidizing bitumens to suit them for particular applications were gradually perfected.

Then came the call for more and more aviation spirit, a product which had hitherto been considered of negligible importance and the small demand for which had been met by a volatile motor spirit. To-day it is a complex mixture of carefully selected components made by a variety of processes, and refiners are concerned not only with its production in vast quantities, but also in maintaining a high standard of purity.

In the early days of the industry there was a deplorable wastage of natural gas. Now it is harnessed for use in a variety of ways. The dry gas is used as a gaseous fuel in refineries and for industrial purposes, also for the manufacture of hydrogen by thermal decomposition and the production of carbon black by incomplete combustion. Ethane is cracked into the reactive unsaturated hydrocarbon ethylene from which by interaction with iso-butane is obtained neo-hexane, a valuable component of aviation spirit. "Bottled-gas" is produced by liquefaction of butane and propane by pressure at ordinary temperatures and is distributed in steel bottles for domestic cooking and lighting.

Finally, brief mention was made by Mr. Kewley of the ever-increasing number of special oils of the lubricating class, of the numerous new applications of paraffin waxes in the electrical and waterproofing industries, and of the uses to which are put the waste products from various refining processes, for example, naphthenic acids and cresylic acids.

All these data are amassed in support of the main theme of the paper, which is to demonstrate how successfully the petroleum industry has adapted itself to current demands and at the same time to adduce evidence pointing to the maintenance of this process of evolution in all its intricacies.

THE LIGHTNING DISCHARGE

AN official communication (Ref. *S/T* 18*a*) from the British Electrical and Allied Industries Research Association upon this subject has been published by C. E. R. Bruce and R. H. Golde (*J. Inst. Elec. Eng.*, Pt. II, Dec., 1941). The contribution is an important one, and it presents several new theses. It is considered that the potential required to cause a lightning discharge is only a small percentage of that hitherto believed necessary, namely, of the order of 5×10^7 volts as compared with Wilson's 1×10^9 to 6×10^9 volts. The energy involved in a flash is of the order of 250 kwh., while the average charge is of the order of 50 coulombs, or 50 per cent greater than had been previously accepted. About one third of this charge is probably neutralized in the intervening space charge.

Available statistical data show that thunderstorms all over the world have similar flash time characteristics and numbers of strokes per flash. Strokes to the Empire State Building, New York, were found to be similar in overall duration to those occurring in ordinary country, due allowance being made for the duration of the initial continuing stroke. The currents in the flashes, however, were greater than those in flashes to normal country. Evidence purporting to suggest that storms in temperate regions vary in the number of strokes per flash was found to be inconclusive, and it is suggested that the later strokes of a flash are less intense than the earlier ones. These successive strokes are initiated by streamers *from* the original stroke *to* other cloud centres, and it is thought that strokes to transmission line conductors which do not cause flashover are unlikely to be followed by subsequent strokes.

Support was obtained for the suggestion that the wave forms of atmospherics are due to successive reflexions from the ionosphere and not to current pulsations in the lightning channel.

Negative flashes to earth are more frequent than positive flashes, the ratio being considerably smaller in temperate than in tropical regions. The polarities of direct strokes to transmission lines are unobtainable from magnetic-link observations on transmission towers. A higher proportion of positive currents has been observed by the cathode ray oscillograph as compared with negative currents.

Norinder's values for individual stroke currents are shown to be in error, an important selective principle having been neglected when comparing these with magnetic-link data.

SOUTH AFRICAN PREHISTORY

A NUMBER of interesting articles are contained in the *Transactions of the Rhodesia Scientific Association*, 37 (April, 1941). It is good to learn that the study of the rock-shelter paintings of Southern Rhodesia continues, and the Hon. L. Cripps speaks of thousands of sites of which he has visited and made copies of paintings at some six hundred. This is no mean work, and his little paper, scientifically written so far as it goes, is, one hopes, only the precursor of a larger work. The author has continued to study the superpositions of the different coloured paintings (though making no mention of any changes of style or subject-matter) and by these means makes out an age-colour sequence not materially differing from that which I was able to suggest in 1928. Further, he considers that the paintings were connected with the burial of the dead, and that the present-day natives are the descendants of the artists. I venture to suggest that some at least of the paintings go back to a very remote period, and that much migration into the country has taken place since they were made. It is always difficult to deny continuity of blood in any given instance, but I doubt whether there is any general direct descent from the earliest painters to the modern inhabitants. Indeed, I am not even sure that the painters in claret were themselves the direct descendants of those who used the earlier colours. May I perhaps remind Mr. Cripps that the problem of dating the paintings will surely involve excavations in the sites and that Bambata and Nswatugi seem to point the way and have in fact already helped in this direction ?

Mr. K. Radcliffe-Robinson describes a Stone Age industry from the Wedza district, some three hundred yards from the Sabi River on the banks of a tributary. Dolerite is the chief material used. Implements of various types occur, and, if the industry is really homogeneous, the age cannot be very remote, although some handaxe-like types and a possible burin occur. But so does a polished tool ! The occurrence of burins in more or less recent levels has been noted by Schofield in Natal, and rough core tools somewhat of a handaxe type are also not unknown. The technique of polishing is not very common, but examples are known from Southern Rhodesia, and farther to the south, for example, there are local specimens in the Museum at Grahamstown. In no case does this technique appear to be very ancient so far as we can determine. At a part of the site a little distant from the main mass of these tools there was found a Rhodesian Stillbay industry of quartz and ironstone, but owing to the lack of any stratigraphy it is, as is so sadly usual in this country, impossible to prove any relative dating of the two industries. This paper, too, shows a scientific attitude to the problems of Rhodesian prehistory; the drawings are adequate but might have been better arranged.

Mr. C. Martin describes pottery-making in Nanyikaland, an art which is apparently dying out. As usual in Bantu tribes, pottery-making is woman's work. A good description and some interesting photographs are given.

M. C. BURKITT.

DRUG PRODUCTION IN THE BRITISH EMPIRE

IN a paper on "British Empire Drug Production" before the Royal Society of Arts on December 16 (*J. Roy. Soc. Arts*, 90, 138; 1942), Dr. Maurice Ashby points out that we are normally dependent on imports from overseas for practically the whole of our requirements of crude drugs, and a large proportion of our pre-war imports came from countries outside the Empire, the continent of Europe being our main source of supply of such vital drugs as belladonna, digitalis, henbane and stramonium. Dr. Ashby, after emphasizing the difficulties which might be encountered, owing to the influence of environment and inherent physiological differences, in growing medicinal plants in a new country where the climate or soil conditions might not be quite the same as in its original home, gave an encouraging account of what is being done in Empire countries to meet essential needs.

In Canada the most important development is the introduction of cascara as a crop, but some years will be required before supplies are available from the new plantings. In Australia and New Zealand the two most important items are agar-agar and ergot, and both Australia and New Zealand appear hopeful of producing really good-quality agar on a commercial scale.

Large-scale experiments on the artificial production of ergot on rye were undertaken in Australia on behalf of the British Government. New Zealand could probably produce most of the medicinal herbs we formerly imported from Central Europe, but the high cost of labour would make this uneconomic. With regard to India, Burma, Ceylon and Malaya, about 90 per cent of the world's supply of cinchona bark came from Java, which holds a virtual monopoly of the market. Indian production is still largely confined to Bengal and Madras, and has always aimed at satisfying local needs. Cinchona cultivation has been revived in Ceylon in recent years and there has also been experimental work in Malaya and Tanganyika. We have flourishing ipecacuanha industries in Bengal and Malaya but the quantities produced are very small, South America, particularly Brazil, being practically the only source of supply and, as ipecacuanha is a difficult crop to grow and takes some three years to mature, development must be slow. Malaya is also the leading producer of derris root, and strains have been developed with a far higher rotenone content than the original wild material or that produced by other countries.

The citronella oil industry of Ceylon has now assumed added importance, while in India karaya gum is proving a satisfactory substitute for some of the more costly gums like gum tragacanth and gum arabic. The Himalayas offer endless possibilities for belladonna, henbane, etc.

In the Mediterranean area the chief items are liquorice root and squill, particularly in Cyprus and Palestine. From South Africa the chief drug products are Cape aloes and buchu leaves. Cascara production in East Africa has been moderately successful and there has been experimental work on ephedra and on ocimum oils as a source of camphor, but the most striking success has been the pyrethrum industry.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chief Assistant to the Ayrshire Electricity Board—The Clerk to the Ayrshire Electricity Board, Greenholm Street, Kilmarnock (endorsed 'Chief Assistant') (March 2).

Senior Lecturer in Pathology, and a Junior Lecturer in Pathology—The Secretary, Royal (Dick) Veterinary College, Summerhall, Edinburgh 9 (March 16).

Demonstrator in Botany at Westfield College, University of London—The Registrar, Westfield College, at St. Peter's Hall, Oxford.

Assistant Chemists, partly for Laboratory and partly for Process Plant Operation, for employment in the East—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Hanway House, Red Lion Square, London, W.C.1.

Colloid Chemist or Physicist—The Director of Research, British Pottery Research Association, Queens Road, Penkhull, Stoke-on-Trent.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Saturday, February 21

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 2 p.m.—Mr. L. C. Maitland: "Mining Timber, Possible Economies and Substitutes".

Monday, February 23

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W.C.2), at 2.30 p.m.—Prof. J. Beattie: "Physical and Chemical Changes in the Blood associated with Shock and Hæmorrhage".

Royal Geographical Society (at Kensington Gore, London S.W.7), at 5 p.m.—Geographical Films.

Tuesday, February 24

Royal Society of Arts (Dominions and Colonies Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Prof. C. W. Wardlaw: "Banana Research at the Imperial College of Tropical Agriculture, Trinidad".

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Mr. Ewart G. Culpin: "Reconstruction after the War, with special reference to the Problems of Town and Country Planning".*

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W.C.2), at 2.30 p.m.—Prof. J. Beattie: "Physical and Chemical Changes in the Blood associated with Shock and Hæmorrhage".

Institute of Physics (Joint Meeting of the London and Home Counties' Branch and the Royal Photographic Society) (at the Royal Photographic Society, 16 Princes Gate, London, S.W.7), at 5 p.m.—Mr. E. R. Davies: "The Role of Photography in the Detection and Measurement of Radiation".

Wednesday, February 25

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. James Hogan: "The Post-War Home—its Interior and Equipment". 6: "Pottery, Glass and Plastics".

Coke Oven Managers' Association (Joint Meeting with the Institute of Fuel together with the Iron and Steel Institute and the Institution of Gas Engineers) (at the Royal Victoria Station Hotel, Sheffield), at 2.30 p.m.—Mr. J. G. Bennett: "The Future of Coke".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Dr. K. S. Sandford: "The Geology of Italian North Africa".

Thursday, February 26

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Rt. Hon. the Earl of Onslow, G.B.E.: "The Preservation of the Existing Fauna of Great Gritain in a Wild State after the War".*

Friday, February 27

Institution of Mechanical Engineers (at Storey's Gate, London, S.W.1), at 2.30 p.m.—Mr. Hal Gutteridge: "Proneness to Damage of Plant through Enemy Action".

British Institution of Radio Engineers (Midland Section) (at James Watt Memorial Institute, York House, Great Charles Street, Birmingham 3), at 6 p.m.—Mr. G. Bernard Baker: "Thermionic Frequency Control".

Saturday, February 28

Royal Sanitary Institute (at the Nuffield Institute of Clinical Research, Oxford), at 10 a.m.—Mr. H. H. Crawley: "The Storage of Emergency Drinking Supplies"; Mr. Stewart Smith: "Administration of the Government Evacuation Scheme".

Nutrition Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10.30 a.m.—Conference on "Food Production and Distribution in relation to Nutritional Needs". (Speakers: Sir John Orr, F R.S., Dr. N. C. Wright, Mr. E. T. Halnan, and Sir John Russell, F.R.S.)

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

BIOLOGISTS IN WAR-TIME

'GUNS not butter' may have some merit as a war slogan but cannot be considered a good axiom for warfare. Without fats, with their high calorific value, there would not be the muscular energy to build more guns. In the strategical planning of modern wars the only sound precept is—guns *and* butter. Under conditions of emergency or unpreparedness it may be necessary to concentrate upon gun-production and neglect butter-making. This state of affairs existed in Great Britain before and during the early phases of the War, and the urgency of the demand for guns, tanks and aeroplanes, with all their associated equipment, laid great stress on the part the physicist, chemist, metallurgist and engineer could play in development and research.

Biologists during this first period of crisis well realized that they could not expect to be regarded as essential cogs in the war machine. They did, however, feel that as the first crisis passed, it would become evident that biologists had a contribution to make to the war effort. The Government was known to have recognized that the prolonged storage of reserves of grain and other foodstuffs is associated with special war problems concerned with mould, insect and rodent attack. These problems were already being investigated by biologists; it seemed likely that there would be further storage problems to investigate or advise on. In other fields there were encouraging signs that biologists could do useful work. Much attention was being given to the problem of crop failures and the incidence of wire-worms in the soil. There was, therefore, the feeling that there would be more war-time agricultural problems, but there was, however, the sobering reflection that wire-worms in newly ploughed up grassland had been a problem in the War of 1914–18 and that during the intervening decades little had been done to solve it. This was emphasized by Sir John Russell at the Conference on Science and the War Effort organized by the Association of Scientific Workers (see NATURE of February 21, p. 208).

By the middle of 1940 biologists first began to realize that they could not be expected to be directed into war work of a biological nature without themselves taking active steps to inquire whether problems existed or whether their biological knowledge could be put to a useful purpose. Already there was a tendency, not only among intelligent laymen but also among other men of science, to assume that in this War there was no place for biology—apart from the medical aspects—except in a few narrow fields. This attitude was not surprising, for to the non-biologist the progress in many other sciences, compared to that in biology, appears like the race between the tortoise and the hare. After a year of war the contest seemed even more unequal, and the physical sciences had a start. From the outset engineers, physicists and chemists had been mobilized in large teams to work in such specialized fields as radio location, chemical warfare and aeroplane design. Biologists in general had not had the advantage of co-ordinated team work. They also had the further handicap that many biological developments cannot have the dramatic appeal of the technical developments which lead to the production of a new fighter or a more effective bomb. Misunderstandings, too, concerning the importance of certain branches of biological research and results have also played a serious part during this War, as emphasized by Dr. A. Walton at the Conference to which reference is made above.

Another aspect of this unequal expansion of non-biological and biological research led to a large demand, especially in radio location, for biologists with a knowledge of physics. As a result many biologists who saw no prospect of being employed in a biological capacity joined up as technicians in the Services. To other biologists, who by this time were convinced that there were biological problems to be solved, this progressive depletion of the ranks was more than disturbing. There was also the further cause for anxiety since objections were sometimes raised that biological research was essentially long-range and therefore could not be brought to a successful conclusion in war-time. In agriculture, many of the research stations had lost most of their research staff for advisory work under the county war executive committees. This policy had the advantage of capitalizing the knowledge of experts in advising farmers, but had the disadvantage that simultaneous research at a number of research stations, so essential if reliable results are to be obtained in a minimum time, was seriously handicapped for lack of facilities.

Although in agriculture this switching of biologists from research to advisory duties indicated an official recognition that research workers are capable of making constructive use of their research experience, in other spheres there seemed to be little realization that a large capital of knowledge existed among biologists which if properly employed would return a handsome dividend. Biologists were convinced that wherever biological material was used or stored in large quantities there must be biological problems connected with supply, preservation, provision of substitutes, etc. Some of the problems, it was felt, were capable of immediate solution or only required short-range research. What appeared to be lacking was the appreciation that the problems existed and the absence of any mechanism by which information could be obtained or contacts established.

This was the background in the early part of 1941 when the Association of Applied Biologists, the British Ecological Society and the Society for Experimental Biology agreed to form a joint committee to consider what was the role of biology in war-time, what parts biologists could most effectively play and how their services or biological knowledge could best be brought to bear both on the problems and on the prosecution of the War.

As announced on p. 238 of this issue, a committee —the Biology War Committee—has now been set up which is recognized by the Government and is linked to a new joint committee of the Department of Scientific and Industrial Research, the Medical Research Council and the Agricultural Research Council.

The formation of this Committee is an important step forward and we heartily congratulate the three Societies on the important step they have achieved. Under the new procedure, biologists now have a channel through which problems, suggestions or ideas can be transmitted to the joint committee of the three Government research organizations and through it to other Government departments or the Services. Similarly, biological problems encountered by these departments or requests for information can be referred back to biologists through the same channel. In this connexion it is clear that if the proper contacts are to be established and the most correct information obtained, the Biology War Committee must be aware of the workers and their research in all the main biological fields. The course that the Committee has adopted initially of co-opting members so that each field of biology is represented by an expert is, in war-time, the only possible one if the Committee is from the outset to maintain the fullest liaison with biologists.

The setting up of this organization raises a number of important questions concerning the relationship of biology—excluding the medical aspects—to the community not only in war but also in peace. That such a committee should be in being only after two and a half years of war reflects the failure of the community as a whole to appreciate the true implications of biology and the part it has to play under war-time conditions. This lack of appreciation cannot be laid at a single door, but is brought about by a variety of causes. First, the teaching of biology in schools has had until recently scant attention compared to the teaching of physics and chemistry. Secondly, in the past the curricula of school biology have had a sterile academic flavour and little stress has been laid on how biology directly affects the lives of individuals. To-day in this respect there are indications of change, but the change has come too late to affect appreciably as yet the general outlook.

Furthermore, this welcome modification of biology from that of 'pure' botany plus zoology to the more comprehensive science of man and mankind is still being opposed by powerful authorities. Too many biologists still 'pride' themselves on their ignorance of the impact of their science on society.

Many biologists in our universities still look askance at applied biology. That outlook has had its repercussions right down to our primary schools, and herein, we think, lies the reason for the prevalent view, held even in many authoritative circles, that there can be very little *direct* use for biologists in our war effort. We welcome the founding of the Biology War Committee if only for the purpose of dispelling this out-of-date view; and, perhaps the Committee will succeed in rousing other biologists to their social responsibilities. The Committee might have another effect—that of counteracting the attempts of some biologists to disturb the relations of modern science to society under the pretext of preserving the freedom of scientific research. The establishment of this Committee in no way jeopardizes scientific freedom; rather will it help in the long run to preserve it.

The discoveries and technical developments of the non-biological sciences impinge directly on the life of every citizen, and it is literally brought home to him that science is affecting his way of life. That is seen especially in the sciences of physics, chemistry and engineering, in the development of radio, plastics and the motor-car. Because of his everyday familiarity with these products of science he learns to appreciate that each is a specialized field. He fully comprehends that a motor-car mechanic is not likely to be able to repair a radio set, and generally realizes that experts who design motor-cars do not design radio gramophones. But when it comes to biology, except perhaps in the farming community, biologists, when not classed as medical men, anthropologists or psychologists, may be distinguished as botanists and zoologists but no further. The idea is still prevalent that the sciences of botany and zoology are not like physics and chemistry, that is, widespread in their many fields, but sciences in which all branches come within the orbit of a single individual. It is not uncommon to find that a botanist's primary function is regarded as his ability to identify and classify plants, and it comes as a shock to learn that botanists may be interested in other things for which a knowledge of the physical sciences and mathematics is essential. For this prevailing view the biologists have largely themselves to blame. Is there, for example, any science other than biology which has found it necessary to form a society to deal especially with its 'applied' aspects. Yet nearly forty years ago certain more progressive biologists felt the need for such a society and thus founded the Society of Applied Biologists, which deals with those aspects of biology which ought to come within the purview of any general biological society. This Society, together with others equally as progressive and broad-minded, is now the very one to turn its attention to the value of its work to the war effort.

This misunderstanding of the scope and breadth of the biological field is in peace and war a serious handicap to the appreciation of what are biological problems or to what extent biologists can help in solving them or even preventing them arising. This misunderstanding brings in its train other misapprehensions. It is not always realized that biologists are not all equally competent to deal with every biological problem, and that for a given problem there is likely to be one kind of biologist who can solve it most effectively. It is not appreciated that most biological problems are complex and may for their solution require the united efforts of several different specialists not all of whom may be biologists. Nor is it fully understood that biologists have an important contribution to make by suggesting preventive measures.

It is to be hoped that the Biology War Committee by its activities will demonstrate how wide are the fields that the biological sciences cover and so bring home the value of biological research and study. The approach must, however, be twofold and the community educated to adopt a more biological outlook. As Sir John Graham Kerr points out in his communication in NATURE of February 21, p. 221, the training of biologists is at the present time at a discount though the lessons of biological study may find their application in the design of the fuselage of fighter aircraft or the correct size of a Government department. Biologists, in this respect, are, as we have already pointed out, themselves much to blame. They have not sufficiently brought home to themselves or to the layman that, apart from food production and dietetics, biology is concerned in such diverse things as corrosion in condenser tubes, the purification of coal gas, the preservation of structures in bombed buildings and the fouling of ships' bottoms.

Now, the foundation of the Biology War Committee, with its strong membership, will be able to change all this. We heartily endorse its being and terms of reference, and feel it is an occasion for congratulation that the Government views it with favour, since this Committee can, and must, do much, not only for our war effort, but also for biology itself. It can raise the science of biology from the slough of complacency in which it has wallowed for decades to the firm road on which it rightly belongs—that of a science not only of cultural value but also of inestimable practical value to the progress and evolution of civilization, a value on a par with that at present attached to the sciences of medicine, engineering, physics and chemistry.

PURITY AND FINE MEASUREMENT

Chemical Species (La Notion d'espèce en chimie)
By Prof. Jean Timmermans. Translated from the revised French manuscript by Prof. Ralph E. Oesper. Pp. ix+177. (London: Macmillan and Co., Ltd., 1941.) 18s. net.

PROF. TIMMERMANS of the University of Brussels and director of the International Bureau of Physico-Chemical Standards, was the author of a book entitled "La Notion d'Espèce en Chimie" which was published in Paris in 1928. This most useful little book has now been amplified to bring it up to date and very satisfactorily translated into English by Dr. Oesper with the title "Chemical Species". The book deals with these questions: What is a chemical species and how can a given physical-chemical system be defined without ambiguity ? How should a substance be refined so that it accords with such definition of purity ? And what precautions are necessary in the precise measurements of its constants ? There is much available data in the literature, good, bad and indifferent, but it is not always easy to know which are the best values to choose. Richter, the editor of "Beilstein", in an article on how that great handbook was compiled wrote, "the principles to be followed in such critical choices have been laid down by Timmermans": they will be found in Part IV of "Chemical Species".

The book is not a treatise; it is a statement of principles, illustrated by many interesting notes. Much of it is the common knowledge of chemists, indeed their stock in trade; but it would be difficult to find in any other publication the principles which govern the preparation of a pure substance and the conditions for the determination of its constants with known accuracy collected together and set out in a reasoned way so completely. It would be well that chemists should take note, so that the data which are being continually fed into the literature might carry greater 'weight' in the final assessment of the value of any measured constant.

The author, in discussing the nature of a chemical species, points out that in a thermodynamic system, the phase rule defines the distinction between aggregates, solutions, compounds and elements; for example, change of pressure will alter the composition of a constant boiling (azeotropic) mixture and show that it is not a compound. From the thermodynamic point of view, the mixture of *d*- and *l*- camphoroximes behaves as a single component; mixture is only established by change of configuration as shown by change of rotatory power. Timmermans directs attention to the difference in the position of the maxima in the freezing-point curves and the position of the maxima in curves of specific electrical conductivities for certain alloys and therefore the difficulty of attributing such maxima to the formation of compounds. So much light has been thrown on these questions by X-ray methods and by the studies of Hume-Rothery and others, that it would seem that the characterization of chemical species by X-ray analysis might have received some mention. Such methods have played a part in determining whether the red and yellow forms of lead oxide, cadmium sulphide, etc., are merely polymorphs or whether the difference is structural, and might have been referred to in the interesting discussion in Chapter 5 on polymorphism and isomerism.

There would not be much doubt about the characterization of a crystal of sodium chloride (chlorine isotope 35) as a distinct chemical species, but polymeric mixtures like water in dynamic equilibrium are not so unequivocably definable, and the majority of 'pure' materials do not consist of identical molecules but have to be considered as an intimate tautomeric mixture of different species of molecules. The system can only be completely characterized if the values of the factors determining the equilibrium are known. Such factors, for example, may be photochemical, as in the case of anthracene and dianthracene.

Timmermans discusses in Part I how a chemical system should be defined without ambiguity, and that leads to the question in Part II, how to prepare pure materials which permit the preparation of all possible chemical systems. He praises the work of the English chemists Perkin and Young in the extreme care taken as to the purity of the substances of which the rotatory magnetic power or stoichiometric properties were being determined. The purity required depends on the nature of the constant which is being determined; for example, a very small fraction of air in carbon dioxide will affect the critical pressure, but it might have little effect on other properties. There are many tricks in the preparation of pure organic substances; thus, the solubility of secondary butyl alcohol in water is very sensitive to presence of alcohols or ketones, so in making a pure specimen for solubility determination it is no use trying to reduce methyl ethyl ketone, for the reduction is never complete enough. Saponification of a non-volatile ester is also of little use because traces of alcohol remain from the alcoholic potash employed; by preparing the crystallizable monoester of the dibasic acid (phthalic acid), however, the danger of any contaminant during saponification is avoided. There are tricks, but many pitfalls, too; for example, the boiling point of benzene (b.p. 80·2°) is only changed 0·01° C. by 4 per cent of heptane (b.p. 98·4°). The use of adsorbents, drying agents, etc., the determination of constants as criteria of purity, the discussion of errors, the weighting of observations, units and the selection of standards of reference are some of the matters with which Parts II and III are concerned.

It is perhaps not generally realized how many stages are involved in the determination of temperature by means of a mercury thermometer. First there is the observation on the particular thermometer used with the determination errors of the particular observation (stem correction, etc.), then there is the comparison of the thermometer against a standardized thermometer, those are two stages. The standardized thermometer has to be compared from time to time with a thermometer used in the comparison baths at the standardizing laboratory; these would be standardized from time to time against a thermometer which is referred to the platinum resistance thermometer, which in turn has been referred to the gas scale by the elaborate investigations which have established the scale. Those are at least three further stages.

One of the most useful parts of the book is Part IV where examples will be found of determinations of physical constants and the weight to be given to such determinations. On p. 164 reference is made to the measurements of the critical point of benzene as an illustration of the weights to give to values found in the literature: the remark that the value measured by Sajotchewsky in 1879 which differs by nearly three per cent from the accepted value was 'very good', no doubt means that it was of passable accuracy at the early date when the measurements were made, but it would be a poor determination these days.

The final chapter refers to the great need for the provision of pure materials and the careful determination of their constants. Have not so many of the great advances in the past (for example, the discovery of argon) been made in this very quest?

A. C. Egerton.

THE LIFE AND WORK OF WILLIAM HALLOCK PARK

The Man Who Lived for To-morrow

A Biography of William Hallock Park, M.D. By Wade W. Oliver. Pp. 507. (New York: E. P. Dutton and Co., Inc., 1941.) 3.75 dollars.

ROBERT BRIDGES in a letter to Mrs. Henry Bradley, commented in these terms on his memoir of her late husband, the philologist, and one who had been for long his close friend: "It is a first essential in such literary portraits to write something which will engage the reader's attention." When judged by this test, Dr. Wade Oliver's book is a notable success, for it gives the reader a firm and attractive outline of the life and character of Dr. William Hallock Park and of the setting in which his work was done. Dr. Park was for many years director of the research laboratory of the Board of Health in New York City, and he held a well-earned reputation as an exponent of the first rank in the field of applied immunology. Not only so, but he also gained the respect and affection of the leaders of medical research throughout the world, as is witnessed by the generous tributes that were paid to him on the occasion, in October 1936, of the opening of the new laboratories in New York which were rightly named after him.

Park was truly a citizen of New York. Here, on December 30, 1863, he was born, and after a career at school and college which gave no promise of his mature qualities, he led a life of unremitting service in the application of microbiological knowledge to the control of epidemic diseases. He died on April 6, 1939, when he had passed his seventy-fifth year. As a medical student and also as a young graduate, he came under the influence of Dr. T. M. Prudden who, in 1885, was the first to teach medical bacteriology in New York City, and it was to him that Park owed his final choice of a vocation. For a time, however, his gropings in other directions showed him to be irresponsive to his real calling. Thus he graduated in medicine from a desire to become a medical missionary in Persia and in this way to maintain a family tradition. A post-graduate training in Vienna included courses in diseases of the nose and throat and in gynæcology. On his return to New York he was undecided whether to specialize in one or the other of these subjects, until a letter he wrote remained unanswered and in a moment of pique he resolved to practise as a throat specialist, and so became interested in the clinical features of diphtheria and the existing views on its bacteriology. Prudden, who had reached the wrong conclusion that Streptococcus and not the Klebs-Loeffler bacillus was the causal agent of the disease, offered to Park laboratory facilities to investigate the problem in his spare time, with the result that after two years work the etiological role of the diphtheria bacillus was clearly established.

Park's association with the Department of Health of New York City began in 1893 with his appointment to the modest post of inspector and diagnostician of diphtheria. His interest in the prevention and treatment of diphtheria by means of specific immunizing reagents never waned: he was indeed a pioneer in organizing the prophylactic immunization of children on a large scale. Thus, on May 15, 1933, when nearly seventy years old, he immunized, with due ceremony, the millionth New York City child against the disease; and his colleague, Bela Schick, the originator of the Schick test, performed the same service for the first child of the second million.

Park entered the stage of his life's work at an opportune and fortunate time, because then the new science of bacteriology was becoming more and more linked with the ancient study of epidemics, and was helping to free it from the baseless and often fantastic ideas of the older writers. The story which Dr. Oliver so skilfully unfolds of the epidemic history of New York is an enlightening one. In 1892 there were 241 cases of typhus fever with 45 deaths, and 10 cases of epidemic cholera with 9 deaths. In 1904 and 1905 a heavy epidemic of cerebrospinal fever and pneumonia fell upon the city; and in the latter year 3,585 cases of typhoid fever were reported in the Greater City of New York. Again, in the five months from June 1 to November 15, 1916, 8,928 cases of poliomyelitis were notified in this area. The pandemic year of 1918 accounted for 10,886 deaths from influenza and 9,722 deaths from pneumonia in the period September 15–November 16 in New York City. Park's ardour in fighting these plagues never cooled, and he published numerous papers on his investigations, either alone or jointly with his colleagues, who regarded him as an inspiring chief and who served him well.

A chapter is devoted to the problem of the contamination of milk and to Park's efforts to bring about improvements. Reference, too, is made to the discovery of the first case of a chronic typhoid carrier in the United States. Dr. George Soper, who tracked down the house epidemics for which this carrier was responsible, has contributed elsewhere a most interesting account of his inquiries ("The Curious Career of Typhoid Mary", *Bull. New York Acad. Med.*, **15**, 698–712; 1939); the bacteriological work was carried out in Park's laboratory. The sinister figure of Mary Mallon, who was either wholly heartless, or utterly ignorant, or was compounded of both these defects of mind and character, is likely to remain an historic warning of the tragedies which may follow the uncontrolled activities of a potential focus of infection in the person of a typhoid carrier.

Park's success as a director of research was founded on his simple and, at times, almost naive nature, and was supported by his patience, his perseverance and the integrity of his aims; he had a constant desire to help his fellows. He possessed a quiet sense of humour and revealed firmness of mind when the need arose.

The author of this book manifests an apt and pleasing choice in the quotations with which he prefaces the chapters. The portrait of his subject is worthily drawn, and the publishers also deserve praise for their part in the production of the volume.

MAN'S ACHIEVEMENT OF FLIGHT

The Birth of Flight

An Anthology by Hartley Kemball Cook. Pp. 204+8 plates. (London: George Allen and Unwin, Ltd., 1941.) 7*s*. 6*d*. net.

On December 17, 1903, the Wright Brothers made that flight of twelve seconds in a power-driven controlled heavier-than-air machine which was to change the history of the world. The aeroplane has, in a few flying years, altered the outlook of every man and woman in the world, whether he or she has ever flown or not, or even seen an aeroplane. When this War ends, it will alter it still more, for flying will be as much of the world's everyday experience as travelling by rail or steamer is now.

"The Birth of Flight" is a pleasant corrective to the present attitude towards flying. It begins with the mythology and ends with the accomplishment of flight. Much is from contemporary records. In 1670 we find Francesco Lana, who considered air-exhausted spheres acting as balloons, writing, "God would never allow such a machine to be successful since it would create many disturbances in the Civil and Political Government of Mankind." Its success has certainly borne out Lana's prediction, though his theology was wrong. The Royal Society, not long after its foundation, made some inquiries into the art of flying and drew from Dr. Henry Stubbe the caustic comment that "flying was an art in which they have not as much as effected the most facile part of the attempt, which is to break their necks".

In 1783 Montgolfier flew his first hot-air balloon, quickly followed by the hydrogen balloon. For the first time man left the ground and Walpole wrote, "all our views are directed to the air." In a few years France and England had become balloon-minded.

In 1785 Dr. Jefferies crossed the Channel in a balloon, causing as much sensation as Blériot did well over a century later. In the 1860's Coxwell and Glaisher reached a height of seven miles. The balloon played its part in the American Civil War, in the Franco-Prussian War, and a balloon section was formed in the British Army, out of which ultimately came the Royal Flying Corps and the Royal Air Force. Now we have the balloon barrage.

The author only briefly touches upon the coming of the aeroplane. There is, however, one quotation worth recording, from an interview given by Rudolph Martin, a German: "In a world war Germany would have to spend millions on motor airships and a similar amount on aeroplanes to transport 350,000 men in half an hour during the night from Calais to Dover. Even to-day the landing of a large German army in England is a mere matter of money." As the author comments: "there is not enough money in the world for the purpose."

The author has chosen here and there from the story of the conquest of the air, and has chosen well. This is a book for quiet reflection, for those moments when the alarm has not been sounded, for a consideration of those words of Camille Flammarion, in the nineteenth century, writing of the coming conquest of the air: "There would no longer be frontiers but only peoples, and the whole earth will be a Confederation of United States, living in might and liberty."

J. L. PRITCHARD.

A FRENCHMAN'S VIEW OF PREHISTORY

Prehistory

By Prof. A. Vayson de Pradenne. Authorized translation by Ernest F. Row. Pp. 239. (London: The Scientific Book Club, 1941.) 2*s*. 6*d*.

ORIGINALLY trained as an engineer, M. Vayson de Pradenne was a well-to-do Frenchman with a château in Vaucluse and a flat in Paris, a married man with children. Towards the beginning of the present War tragedy overwhelmed the family. With the exception of one child, all were killed in the Paris flat by fumes from a defective stove. Vayson had for long been interested in prehistory, especially in the earlier periods. He bought up nearly the whole of the vast collection of Lower Palæolithic tools so carefully got together by the late V. Commont from the gravels of the Somme in the Amiens district, and had intended, later in life, to write for it a *catalogue raisonné*. He brought to bear on the whole subject a keen and trenchant mind and was only too happy to differ from the accepted or orthodox views. His common-sense outlook on a problem was often like a breath of fresh air in a crowded room—even if to some of the inmates it may have been felt as a draught! He was accorded the titles of "Directeur à l'école des Hautes Études" and "Professeur à l'école d'Anthropologie", and he also had a finger in the pie at the Trocadero, but none of these posts involved any regular teaching or research. Indeed, Vayson always remained the amateur—with the merits and faults of his kind.

Though the reviewer, himself a 'professional', is one of those who feel strongly that the professional owes a great part of his knowledge of prehistory to the amateur—that the former marches forward to a great extent on the trail blazed by the latter—yet none the less there is usually a lack of co-ordination to be felt in the work of the amateur, a criticism from which Vayson cannot wholly escape. His book is an epitome of himself and gives an excellent general, world-wide survey of his subject extending into Neolithic times. It will not be of much use to the specialist, but for the general reader it will help to stimulate interest in a fascinating branch of study and will serve as an undetailed book of reference to those who, having already a little information, would like a summary of what is known of prehistoric times in this or that part of the world. After all, Vayson was in the inner ring of prehistorians, he knew his subject and was not merely a scissors and paste hack hired by a publisher to write a work on prehistory for the benefit of the latter's pocket!

Part 1 deals with definitions, scope, method, interpretation of data and technology; Part 2 with classifications and chronology in western Europe, and Part 3 with prehistoric material from various parts of the world. There are a number of simple and convenient tables and the illustrations are adequate. There is no bibliography. In the original French version a short, exclusively French, bibliography was appended; it is perhaps a pity that the translator, who has done his work well, did not see fit to add a list of references suitable for English readers and which would have enabled them to delve deeper into the subject had they desired to do so as a result of the stimulus of Vayson's work. Knowing the book in French, one was at first inclined to wonder whether a translation was really called for: whether the book would really fill a gap in English libraries. On the whole it was, however, probably worth while, and one is glad in any event that Vayson's name should be thus perpetuated on our bookshelves.

M. C. BURKITT.

PHYSICAL GEOGRAPHY

The Earth and its Resources

A Modern Physical Geography. By Prof. Vernor C. Finch, Prof. Glenn T. Trewartha and M. H. Shearer. Pp. x+634. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 17*s*.

FROM the title of this book one might expect to find a treatment on fresh lines, with the selection and arrangement of its matter governed by the relevance of the materials to human needs. It is in fact a sound text-book on quite conventional lines. Its relation to a previous work is stated in the preface (p. vi) as "The content and organization have come largely from *Elements of Geography*, a college text by two of the authors. The third author . . . with the background of . . . teaching experience in secondary schools . . . has restated the subject matter for use at that level of instruction." It is added that the accompanying laboratory manual provides sufficient work for two semesters, with a hint that possibly it may be confined to one semester. The book could be used for the physical geography of the last year of the high school; it assumes a good elementary knowledge of the home country (United States of America).

The treatment is deductive in that general principles are simply stated, results are drawn from them and these are then illustrated by particular facts, used as examples. For instance, Chapter 11, p. 288, starts "Imagine that Fig. 186 represents a plain about 500 miles long. A glacier, centred at A, slowly pushes its way southward. . . ." To a reader familiar with the subject it is clear that this hypothetical case is a very simplified version of the glaciation of either North America or Europe. The deductions as to the features of glaciated land are similarly begun from diagrams of theoretical, imagined surfaces which are equally recognizable as generalizations (for example, Figs. 190, 201, 205), each of which is followed by specific examples of the feature discussed.

This kind of treatment may well give the student the impression that our knowledge of the phenomena is obtained from such hypotheses. In fact, as the authors well know, what happened was (1) the observation and record of a large number of facts, (2) comparison and classification of these, (3) the development of possible hypotheses for the generalization and 'explanation' of the facts, (4) the testing of the hypotheses by further observation and survey and, where possible, experiment; and only those hypotheses which have survived this testing are now accepted. While it is true that no text-book can set these steps out in full over the whole of its fields, it would be better to follow this order, so as to leave the student with the knowledge that a scientific hypothesis, or theory, is to be judged by the success with which it fits both the facts it was devised to 'explain' and any other relevant facts which may come to light later. Hence if a better hypothesis is devised, the less satisfactory one will be abandoned. Physical geography contains abundant material for such study; and, as a teaching method, it may well be preferred to the presentation of present-day hypotheses as if they are unquestioned truths.

The book is very well illustrated and produced. Although it is a first edition, the present reviewer has noticed no important error or misprint. The appendixes are, for the most part, useful; but Appendix D, "The Interpretation of Maps", does not add anything to what the pupil should know before reaching this stage; while the seven maps which conclude the volume are quite inadequate to illustrate the work although their presence may be regarded as suggesting that the reader does not need an atlas.

C. B. FAWCETT.

THE SOCIOLOGY OF MEDICINE

Medicine and Mankind

By Arnold Sorsby. Pp. 256+16 plates. (London: Faber and Faber, Ltd., 1941.) 12*s.* 6*d.* net.

ADVANCES in medicine and the allied sciences have of recent years been very great; it is no exaggeration to say that the change both actual and potential in only one generation of time has been exceptional. This increase in degree and direction of knowledge cannot be wholly regarded as technical detail interesting to the practising physician in the conduct of his profession; it comes, on the contrary, directly within the concern of the intelligent man in the street, for the prevention and treatment of disease are matters which impinge immediately upon his personal life. Immunization against diphtheria may be cited as an example; it is now an established method, easy in performance and satisfactory in practice, yet it has been carried out in Great Britain on a scale which can only be described as petty compared with the extent practised in the United States. The difference is almost entirely due to the respective efficiencies of the campaigns bringing the matter to the notice of the general public.

It is not only advantageous in his private life that the ordinary man should have some knowledge of these developments, it is important from a social point of view; public opinion has to be educated to appreciate the trend and movement of work which steadily intrudes more and more into all aspects of human life. For good or ill, man has become a community animal. Civilization brings manifold consequences; it means responsibility as well as advantages. Measures for communal welfare are not brought to efficiency by being placed upon the statute book, but by the active support of an educated public.

Books, therefore, which seek to bring anyone of matriculation standard in touch with the current findings, purposes and possibilities of modern science deserve an important place. "Medicine and Mankind" is of this type. Dr. Sorsby succeeds admirably in the picture he gives of present-day medicine. He is greatly aided in this task by the adoption of a simple straightforward design which allows balance and proportion in the subject-matter.

Dr. Sorsby, opening with an account largely historical of the relations between health and disease and the theses which have governed our attitude at different stages of progress, goes on to a statement of health from the physical point of view. He then proceeds to discuss in sequence the ill-formed body, the ill-balanced body, the abused body and the assaulted body. This enables him to set out in due proportion such diverse subjects as experimental embryology, endocrinology, dietetics, including the accessory food factors, the new dye-stuff medication, allergy and bacteriology. Treatment equally has its place and is conveniently divided into chapters on individual and collective measures.

Under the heading "Social Achievements and Frustrations" Dr. Sorsby takes up various aspects of morbidity, mortality, environment, nutrition, occupation and related factors of importance; this is perhaps his best chapter. While he directs attention to the persistence of many preventable conditions, he avoids polemics on the culpable aspect, for there are, of course, environmental conditions to-day the continuation of which infers ignorance or inattention on the part of responsible public opinion.

Dr. Sorsby is obviously interested in the special problems appertaining to nature and nurture. He therefore allows himself rather more space on questions of genetics and environment, but as these subjects represent an active fringe of medicine, active in its justifiable inferences as well as its real or immediate effects, this latitude cannot be regarded as altogether out of place. He omits all reference to psychological matters. This depends apparently upon a question of space, but the omission in a sense enhances the value of the book. For it allows a restriction of the contents to purely physical aspects which certainly offer enough to think about.

"Medicine and Mankind" is a competent and careful study. It should be of use to the practising physician anxious to keep in touch with the broad lines of thinking medicine; it should also be of use to the man in the street with sufficient intelligence to appreciate his limitations. There are numerous illustrations which have been happily chosen to simplify the subject-matter and enhance its application.

JOSEPH GEOGHEGAN.

THE BIOLOGY WAR COMMITTEE

DURING 1940 meetings were held at which the place of the biological sciences and the role of biologists in war-time were discussed by the British Ecological Society, the Association of Applied Biologists and the Society for Experimental Biology. As a result of these discussions each of the societies appointed a sub-committee to review the position and make further inquiries as to the nature of war problems. Early in 1941 the sub-committee of the societies agreed to form a joint committee and after several meetings formulated a number of proposals as to the best means of mobilizing both biologists and biological knowledge in the national interest.

In May, the Committee of the three societies was informed that the Agricultural Research Council jointly with the Department of Scientific and Industrial Research and the Medical Research Council had considered the proposals as to the application of biological knowledge to problems arising out of war-time conditions and the fuller use of the services of biologists during the War. They had, therefore, created a small Joint Committee to carry out "the declared policy of H.M. Government to make the fullest possible use of science to assist the Nation in its war activities" and to confer "on the further steps which might usefully be taken to carry this policy into effect so far as the biological sciences are concerned". The Joint Committee invited representatives of the Committee of the three societies, as being an organized body dealing with this matter, to meet them, and the following scheme was put before this Joint Committee.

It was proposed that, *vis-à-vis* the Joint Committee of the Government research organizations, the Committee of the three societies should be expanded into a larger committee representative of all the main aspects of biology and that this larger committee—the Biology War Committee—should co-operate with the Government Committee in the following ways:

(1) Act as a clearing-house through which problems or ideas coming from biologists can be brought to the notice of the Joint Committee of the Government and through it transmitted to the appropriate Government Councils or Departments.

(2) Provide a channel by which the Government can refer problems to biologists.

(3) Direct the attention of the Government to any results of current biological research which the Committee considers to be apposite to the war effort.

(4) Prepare reports or memoranda on any aspect of the War which is essentially biological or which has biological implications and to submit such reports to the Joint Committee of the Government research organizations.

In connexion with this scheme the Joint Committee of the Government research organizations wishes to stress that the proposed machinery is to supplement the existing contacts with biologists and in no way seeks to disturb the connexions already established. Heads of university departments, research institutes or research stations who are already in touch with the Department of Scientific and Industrial Research, the Medical Research Council or the Agricultural Research Council would, therefore, continue to communicate direct with the Council or Councils in regard to their recognized field or fields of investigation. Similarly, biologists who are undertaking specific investigations for Government Departments or the research organizations should continue to deal with the Department or Council concerned in regard to those researches in which they are already engaged. With these provisos, the Government Joint Committee is most anxious that, to avoid undesirable complications, biologists shall submit all proposals or suggestions to the Government only through the Biology War Committee.

The original Committee of the three societies, in accordance with the suggestion put forward by the Joint Committee of the Government that the representation of the biological sciences should be as wide as possible, has given careful consideration as to how the original committee should be modified with a view to adequate representation of subjects. It was felt that, while the Committee should cover through its membership the main fields of biology, medicine should not be included, and that the representation should be weighted in favour of those fields which are not highly specialized and in which workers are not already closely linked with the three Government research organizations.

Members of the Committee of the three societies considered that, since at the outset, the work, scope and future of the Committee could not be foreseen, it would be unwise to limit the membership or to draw up a fixed constitution. They were of the opinion that the number of members should not be so great as to impede, especially under war-time conditions, both its efficiency and ability to make rapid decisions, but they also thought that while primarily the representation should be concerned with the main divisions of the biological sciences, yet there should also be some liaison with biological societies. After careful consideration the original committee co-opted fifteen additional biologists, expert in particular fields of biology. Afterwards the Committee approached the biological societies on the question of further liaison. The Committee suggested that, as a preliminary working mechanism for such liaison, biologists, under the exigencies of war-time and in view of the need for the Committee to function as soon as possible, would for the time being accept the arrangement that each biological society would nominate from the existing twenty-three members of the Committee a representative of the Society who would put before the Committee any views that the Society wishes to express and also report to the Society on the activities of the Committee; but here again it must be emphasized that the representation aimed at is that of subjects and not of societies as such.

It is clear that the whole question of the constitution of the Biology War Committee and its relationship with biologists must involve considerable time and discussion with the societies. In view of the fact that a number of biological societies have already offered support to the scheme the Biology War Committee has decided that it should make this preliminary announcement of the formation of the Committee and its personnel to date. It would like again to stress that the composition and numbers are provisional, and it is envisaged that alterations or additions will be made as circumstances arise. The Committee is, so far, constituted as follows:

† * G. E. Blackman (secretary), Department of Botany, Imperial College of Science and Technology, London;

* Prof. W. B. Brierley, Department of Agricultural Botany, University of Reading;

† * Prof. P. A. Buxton (chairman), Department of Medical Entomology, London School of Hygiene;

Prof. H. G. Champion, Imperial Forestry Institute, Oxford;

Prof. A. C. Chibnall, F.R.S., Department of Biochemistry, Imperial College of Science and Technology, London;

Dr. E. M. Crowther, Chemistry Department, Rothamsted Experimental Station, Harpenden;

Dr. C. Elton, Bureau of Animal Populations, University of Oxford;

* Dr. W. P. K. Findlay, Forest Products Research Laboratory, Princes Risborough;

† * Dr. H. Godwin, Botany School, University of Cambridge;

Dr. J. Hammond, F.R.S., Animal Nutrition Research Institute, Cambridge;

Prof. A. C. Hardy, F.R.S., Department of Biology and Oceanography, University College, Hull;

Prof. J. S. Huxley, F.R.S., Zoological Society, London;

† Dr. H. Martin, Long Ashton Research Station, Bristol;

Dr. A. T. R. Mattick, National Institute for Research in Dairying, Shinfield, near Reading;

* Prof. J. W. Munro, Department of Zoology and Applied Entomology, Imperial College of Science and Technology, London;

Dr. J. Needham, F.R.S., School of Biochemistry, University of Cambridge;

Dr. C. F. Pantin, F.R.S. (vice-chairman), Department of Zoology, University of Cambridge;

* Dr. O. W. Richards, Department of Zoology and Applied Entomology, Imperial College of Science and Technology, London;

* Dr. M. A. H. Tincker, The Laboratories, Royal Horticultural Society, Wisley;

† * Dr. C. H. Waddington, Department of Zoology, University of Cambridge;

Dr. T. Wallace, Long Ashton Research Station, Bristol;

Dr. E. B. Worthington, Freshwater Biological Association's Laboratory, Wray Castle;

J. Z. Young, Department of Zoology, University of Oxford.

In conclusion, although the full Committee has only been in existence a short time, it has been very active. The Committee is inquiring into a number of suggestions and problems raised both by biologists and by the Government. These cover a surprising range of topics and many of its activities relate to confidential matters, in respect of some of which the Government has accepted the Committee's proposals.

Biologists who wish to put forward suggestions, proposals or problems under this scheme should communicate with G. E. Blackman, Hon. Secretary, Biology War Committee, Imperial College of Science and Technology, London, S.W.7, or with other members of the Committee. In this connexion it is pointed out that under the terms of reference all such suggestions are communicated to the Joint Committee of the Department of Scientific and Industrial Research, Medical Research Council and Agricultural Research Council which will, if necessary, refer them to the appropriate Government Departments for consideration. In the first instance all suggestions are couched in general terms and in an anonymous form.

---

METEORITES AND THE AGE OF THE SOLAR SYSTEM

By W. J. ARROL, R. B. JACOBI
and PROF. F. A. PANETH

BETWEEN the years 1928 and 1931 several papers on the age of iron meteorites were published, based on analyses of their helium and uranium content[1]. The last paper gave age values for twenty-two iron meteorites which were fairly evenly spread over periods ranging from 100 to 2,800 million years.

It was pointed out in this paper that the helium measurements were considered satisfactory, while the method used for the estimation of uranium still lacked in accuracy and was to be replaced by an improved one[2]. Owing to external circumstances these experiments had to be abandoned after two years, and before final results could be achieved[3]. A new attempt to increase the accuracy of the age determinations was begun in 1937 in the Chemical Laboratories of the Imperial College of Science and Technology in London, and has been continued since 1939 in those of the University of Durham. Since general conditions a while ago again enforced an interruption, we propose to describe here briefly the main alterations made in the method, and the results so far obtained.

(1) The meteorite material used for each determination was increased to 15–20 gm. (2) The large quantities of hydrogen evolved by its dissolution in hydrochloric acid were burned with oxygen in a special device developed in connexion with another problem[4]. (3) Alternatively, the meteorite was dissolved, without evolution of hydrogen, in a reagent consisting of cupric and potassium chlorides and hydrochloric acid. (4) During this process sometimes not only the helium but also the radon liberated from the meteorite was collected and measured[5]. (5) After dissolution, the radium and thorium-X contained in the meteorite were precipitated, together with barium, as sulphates, and converted into chlorides. (6) The thoron and radon evolved from these chloride solutions were measured in an ionization chamber connected with an electrometer valve[6]; the thoron immediately after preparation of the solution in a constant nitrogen stream, the radon after regeneration and transference into the chamber. (7) The α-ray emission from the thoron and radon respectively was recorded photographically[7] over periods of some twenty hours. (8) The radon measurement was repeated at least once after a few weeks time.

The combined effect of these various changes has considerably improved the accuracy of our activity measurements, as control experiments showed. If quantities of radium of the order of 1×10^{-13} gm. (corresponding to an equilibrium amount of uranium of 3×10^{-7} gm.) and of (aged) thorium salts of the order of 1×10^{-6} gm. were added to the reagents, and the radium and thorium-X precipitated and measured as described, the agreement was good within about 10 per cent. It was especially gratifying that it thus became possible for the first time to determine the thorium content of iron meteorites[8]; previously, it was not known to what extent the age values calculated on the basis of the helium and uranium contents only might be too high, but it now appears that consideration of the thorium has little influence on the result, least of all in the case of the oldest meteorites.

In the main, the age values are determined by the helium and uranium content; "uranium" is here understood to comprise "actino-uranium" as well. This isotope, although not a member of the uranium-radium series, is known to be present in constant proportion[9], so that the radon content is a measure of it too. Owing to its comparatively short half-life period, it is responsible for most of the helium[10] in the oldest meteorites, and the somewhat indirect method of its evaluation necessarily introduces a certain degree of inaccuracy which, however, does not seem to exceed that due to the other sources of error[11].

A repetition of the helium and uranium analyses of several of the meteorites examined before 1931 showed that the old helium values are reliable; small corrections in a few cases are without appreciable influence on the main conclusions. The old uranium values, however, were found to be in most cases too high. It is, unfortunately, impossible to give a certain explanation for this deviation; it is not unlikely that most of the large glass vessels[12] used for the meteorite solutions in Königsberg liberated during the time of radon accumulation a sufficient amount of radon from the walls to falsify the figures. Since this assumption, however, cannot now be checked, we give it only as a tentative explanation. There is no doubt about the greater reliability of our present method of determination, into which the various improvements have been introduced; in particular, the small bulbs now used for the accumulation of radon did not, when tested, show of themselves any measurable radon activity.

The lower radon values now obtained made us particularly anxious to convince ourselves that no activity was lost in the process of extraction of radium from the meteorite; for this reason we not only used two different solvents (see above) but tried to compare also in several instances the radon regenerated from the radium-containing solution with the radon occluded in the solid meteorite; the agreement was very satisfactory and does not seem to leave any uncertainty as to the genuineness of the low activities as revealed by our new measurements.

We have concentrated mainly on six iron meteorites chosen for their widely differing helium contents; of the meteorite "Thunda" as many as seven samples were analysed, of the others only two to four. In all cases we feel confident that further investigation will not alter the result greatly, although we hope, in a later resumption of the work, to be able to narrow down the limits of error. These are greatest still in the thorium, and negligible in the helium measurements. (As an illustration of the difficulties arising from the extraordinarily low radioactivity of iron meteorites, it may be mentioned that the average uranium content of a 20-gm. sample causes in our ionization chamber only 8, the thorium content not more than 2, α-rays an hour.) It would take too long to attempt here a discussion of the probable error of the calculated new age values; we give them in round figures to indicate that only approximate data are at present obtainable[13]. We do not believe, however, that the highest ages are wrong by more than ± 1,000 million years, and the lower ones by more than a proportional amount, namely, about 20 per cent.

There is, however, one principal objection which might be raised against all age calculations based on the helium, uranium and thorium content: the fact that beryls and a few other minerals contain more helium than can be accounted for by the disintegration of their uranium and thorium within the geological periods during which they have existed in the solid state. (A helium deficit, caused by the escape of this gas, can occur only in minerals but not in iron meteorites[8].) So long as the origin of this 'surplus helium' is not explained, one has to be sceptical about the reliability of all the age values calculated by the helium method. This point has recently been stressed by Keevil after his discovery that, in addition to the cases of beryllium and potassium minerals detected long ago by the present Lord Rayleigh, some magnetites too contain surplus helium[14]. It will be very interesting to learn whether the magnetites which abound in helium have a peculiar chemical composition, for in the case of beryls it has been shown as very probable that not the suspected element beryllium but some other element, believed to be stable, is actually disintegrating with helium production[15]. The variety in the chemical composition of beryls (which has not yet been critically related to their helium content) gives scope to this possibility. All iron meteorites, on the other hand, are very similar in composition (see below); this, and the fact that, unlike minerals, they do not permit of any helium or radon migration, renders it rather likely that the differences in their helium contents are due to differences in geological age, thus making the application of the helium method possible.

In spite of the present doubt as to the value to be attached to the helium method, we think it worth while here to put our results on record; not only because of our belief that the method is admissible for such uniform and helium-tight material as iron meteorites, but also because we think it necessary to correct our old experimental figures, irrespective of the certainty of their interpretation. If age values of iron meteorites are to be mentioned at all, the results given here and not those previously found should be quoted. Moreover, the radioactivity of iron meteorites has been used in the discussion of geophysical questions; these calculations too will have to be revised in the light of our new measurements.

In Table 1 we have entered against each meteorite the class it belongs to (O = octahedrite, H = hexahedrite, f = fine, m = medium, g = coarse), its nickel,

uranium, thorium and helium content, and, in the last column but one, the age calculated from the three preceding figures. The following conclusions can obviously be drawn. (1) The helium content of the six iron meteorites studied varies greatly. (2) The uranium and thorium contents of these meteorites are confined within narrow limits; considering the still somewhat unsatisfactory state of our activity measurements we are not sure whether these variations exceed those found occasionally in samples of one and the same meteorite. (3) The remarkable uniformity in the uranium and thorium content is in good agreement with the great similarity displayed by all iron meteorites in their main chemical composition as indicated by the percentage of nickel in the above table, the rest being practically all iron. It may be added that it has been shown that all of them contain about 0·6 per cent cobalt, and traces of copper, chromium, carbon, sulphur, phosphorus, and of most of the other elements for which the methods of detection are sensitive enough; the quantities in which these elements are represented[16] scarcely vary from one meteorite to another to an extent exceeding the possible limits of analytical error. (4) The ages calculated for the three meteorites with the highest helium content amount to 6,000 and 7,000 million years.

This last result is of special interest if compared with current views on the age of the earth, the solar system, or the universe. A few years ago there seemed to be reasons to believe that the highest age found by radioactive methods for rocks and minerals in the earth's crust, about 2,000 million years, coincided with the age found by entirely different methods for the solar system or the universe[17]— a rather surprising result. The authors of a more recent survey[18] come to the conclusion that various astronomical lines of evidence make it probable that the universe must be less than 10^{10} years old, without, however, giving a lower limit. If our highest figures for the age of meteorites are considered together with the evidence implying that meteorites have since their formation been members of the solar system[19], we are led to the conclusion that the age of the solar system cannot be less than 7,000 million years, that is, considerably more than the age of the oldest rocks in the earth's crust. This figure would definitely exclude an age of only 2,000 million years which a bold extrapolation from the data of the 'expanding universe' seems to suggest.

It might be asked whether there is much chance that a search among other iron meteorites would discover some with greater quantities of helium, indicating still higher ages. It may, therefore, be useful to give here a list, which includes the values published in 1931 and later measurements, of all the iron meteorites so far examined for helium. It appears that among fifty there is none exceeding the helium content of the meteorite "Mt. Ayliff" included in Table 1. Altogether there are about 450 iron meteorites in museums; but the probability of finding one with much more helium does not seem to be great, considering that, beyond a helium content of about 10×10^{-6} c.c./gm., the number of specimens within constant helium ranges decreases rapidly. Besides, even a helium content of twice the highest value, namely, 80×10^{-6} c.c./gm., the uranium and thorium content being the same, would raise the age of this hypothetical meteorite to no more than 8,500 million years.

Finally, the similarity of the uranium and thorium content in the six meteorites so far fully analysed justifies an attempt to calculate their ages on the basis of an average value for both these elements. This has been done in the last column of Table 1, assuming the uranium content to be $0{\cdot}7 \times 10^{-8}$ gm./gm. and the thorium content $4{\cdot}0 \times 10^{-8}$ gm./gm. A comparison with the age values calculated on the basis of individual measurements, as given in the last column but one, shows that the figures are not greatly altered. Since it is unlikely that in the near future we shall have an opportunity of measuring the uranium and thorium of the forty-four other meteorites, for the sake of a preliminary rough forecast we have calculated their ages (last column of Table 2), on the assumption that the average activity found for the six iron meteorites in Table 1 is valid for the others as well.

It is not without interest to see how the probable age values are distributed among these fifty meteorites[19], but it should not be forgotten that this column is calculated on the simplifying assumption of constancy of the uranium and thorium content; the last column but one of Table 2, showing the helium content, is, however, based on measurements and, quite apart from the question of age, is worthy of attention. It shows, for example, that some meteorites usually comprised under the same name are clearly distinct. Thus the "Bethany, Goamus" and "Bethany, Amalia" irons, which were recently described as part of the "Gibeon shower"[20], can scarcely all belong to the same fall, since a fine piece of the latter possesses a much higher helium content; and of the four famous "Cape York" meteorites, "Ahnighito" and "Savik" obviously form one group, while "Woman" and "Dog" belong to another—a conclusion not inconsistent with the localities where they have been found[21]. The absence of any detectable helium in iron meteorites of normal chemical composition like "Ahnighito" and "Savik"[22] entitles us to add iron and a few other elements to the list of those[15] which cannot be responsible in beryls for the occurrence of 'surplus helium'.

We hope to discuss these and other minor points when publishing our method and results in greater detail. Our thanks are due to Mr. D. B. Janisch and Dr. E. Glückauf for valuable help in the experiments.

HYPOTHESES NON FINGO

By A. E. BELL
St. Marylebone Grammar School

I THINK it was H. E. Armstrong who once remarked, "we are told that the electron does everything but *how* it does anything we are not informed". The criticism is that the word 'electron' is the name of a thing endowed with all the potential properties it is supposed to explain. Much the same criticism was current at one time about the ether, but the electron has perhaps attained more the status of an induction from a wide range of phenomena, while the ether could never have been ranked as more than a hypothetical entity. All the same, there are obvious difficulties in the way of regarding the electron in the light of a scientific realism: its discontinuous and continuous properties seem out of all possible relation with each other; presumably they defeat our mental imagery because of the incommensurability of perceptual space and time—for this seems to be the crux of the distinction between geometrical and causal laws. One is occasionally struck with a suspicion that there are epistemological implications in modern scientific methods. The division of scientific writers into those who adopt a positivist attitude and those who have reacted towards realism marks, maybe, a difference in the broad conceptions of methodology. There are some writers who, as Burtt has remarked, have inverted the relation and have made a metaphysic out of a method. It is not the aim of this short article to attempt to disentangle the philosophical problems involved in the writings of those who have summarized the modern scientific interpretations of phenomena. This has already been done—at least to some extent—by acknowledged leaders in the fields of philosophy and logic. The burden of this article is that there has been, at least from the time of Huygens and Newton, an ultimate divergence in the conceptions of scientific method and in the philosophy tacitly assumed by men of science.

The best setting in which to view Newton's great achievement is against the background of the great speculative systems his work demolished. Newton held that science must keep close to observed facts at all times, must set itself the task of discovering quantitative laws which might be extended by induction. His well-known polemics against hypotheses expressed his distaste for ideas not derived from empirical study of phenomena. Thus the First Book of his "Optics" begins: "My design in this Book is not to explain the Properties of Light by Hypotheses, but to propose and prove them by reason and experiments. . . ." His attitude was made clearer in a letter to Oldenburg written in July 1672. Here he said ". . . the theory which I propounded, was evinced to me, not by inferring, *it is thus, because it is not otherwise*; . . . but by deriving it from experiments concluding positively and directly. The way therefore to examine it, is, by considering whether the experiments, which I propound, do prove those parts of the theory to which they are applied; or by prosecuting other experiments which the theory may suggest for its examination".

This rebuke to critics like Hooke and Huygens reminds one of his famous general scholium at the end of the "Principia". Here Newton wrote:

"Hitherto I have not been able to discover the cause of those properties of gravity from phenomena, and I frame no hypotheses, *hypotheses non fingo*; for whatever is not deduced from the phenomena is to be called an hypothesis; and hypotheses, whether metaphysical or physical, whether of occult qualities or mechanical, have no place in experimental philosophy. In this philosophy particular propositions are inferred from the phenomena and afterwards rendered general by induction."

It is clear that it was not the mere multiplication of explanatory principles that Newton opposed. The tendency to reduce these to a minimum is found in other writers. Newtonian physics was based on the concepts of matter and force. The atomists went further and attempted to substitute a process of atomic collision for the operation of forces. As Duhem remarked: "The Principia of Newton had scarcely seen the light of day before it aroused the sarcasms of the atomistic clan grouped around Huygens."[1] In their turn the atomists were frequently assailed by the Cartesians. Papin, a more or less orthodox Cartesian, criticized Huygens for supposing that hardness or impenetrability was the essence of bodies, and to this Huygens replied bluntly that the Cartesian doctrine of extension was absurd. Newton perceived that scientific theories could gain no general acceptance so long as they were made dependent on a particular metaphysic: the opposing schools of thought each considered that the others retained occult properties. Burtt considers that Newton regarded an exact mathematical formulation of natural processes as the most that one can achieve[2]. Newton recognized also that there is a considerable problem in the validity of induction and that there is no absolute certainty in the conclusions of physical science.

Huygens discussed this last point at the beginning of his "Traité de la Lumière". Contrasting classical geometry with seventeenth-century physics, he remarked that "whereas the Geometers prove their Propositions by fixed and incontestable Principles, here the Principles are verified by the conclusions to be drawn from them; the nature of these things not allowing of this being done otherwise. It is always possible to attain thereby to a degree of probability which very often is scarcely less than complete proof." Writing to Tschirnhaus in 1687, Huygens explained that in physical research it is impossible to start "except by starting from experiments . . . then by conceiving certain hypotheses upon which experiments must be made. . . ." One is reminded of Whitehead's remark that ". . . it is the establishment of the procedure of taking the consequences seriously that marks the real discovery of a theory". Both these great men of science followed their own methods incompletely. Newton was not empirical about space and time, and Huygens followed the procedure of taking the consequences seriously only up to the point at which his elegant geometrical constructions were threatened. For him, as for Kepler, there was another important bias: the inclination to believe that mathematical elegance is in some way an index to reality.

Newton's concept of gravity may rightly be regarded as an abstraction and an induction from the accumulated work of Kepler, Galilei and others. Duhem[3] has pointed out that the idea of universal gravitation has an interesting history which goes back to the time of Aristotle and includes reference to da Vinci, Copernicus, Mersenne, Galilei, Gilbert, Kepler, Francis Bacon, Roberval and Borelli. The idea attained the status of a true induction only with Newton, just as that of the atom became an induction with the work of Dalton.

What we call a theory may not be possible of attainment through purely inductive processes. Newton's method of rendering laws general by induction is surely possible only if we employ some general principle of correlation: "If an induction is worth making it may be wrong." Recognizing this, men of science have for a long time been prepared to make pretty shaky inductions; Clerk Maxwell admitted as much in his paper on "The Dynamical Evidence of the Molecular Constitution of Bodies". An attitude of provisional belief is in accordance with Huygens's methodology—and the readiness for the purely provisional in the structure of science is one of the more startling anomalies in modern civilization which in all else demands an impossible finality.

The curious feature of Newton's position is that he would not explicitly allow even guiding hypotheses in more than a vague way. But his work shows that his real objection was to hypothetical *entities* rather than to hypotheses essential to the design of an experiment. His concentration on mathematical *relations* and on that *quantity* which, in Kepler's words, is "prior to the other categories", were in the strongest contrast with the metaphysical and deductive system of Descartes. The space and time of Newton's system were not identical with the space and time of ordinary sense experience: they were abstractions. Huygens was unable to understand Newton's more positivist attitude here, and the realist nature of his own conceptions makes him a convenient starting-point from which to derive the second main stream of scientific thought. Huygens might have accepted the term 'correlate' as equivalent to 'hypothesis' but, in the manner of all atomists of that time, his concepts assumed a garb from perceptual phenomena. For him the atom was a potential phenomenon, as it still is for some modern men of science.

The questions we seem to face then are these: What scientific concepts now employed are to be regarded as inductions from phemomena and not mere hypotheses? Is a scientific realism only to be founded by ignoring Newton's misgivings about hypothetical entities? Are there not to-day the same methodological objections to a process of world-building as applied in the seventeenth century to the Cartesian vortices, namely, its remoteness from empiricism and its employment of fictitious entities? It appears to be impossible to lay down hard and fast rules for the distinction of those concepts which satisfy Newton's demands and those which are purely hypothetical. The history of science suggests that in fact the former often develops out of the latter. Newton's general law of universal gravitation developed out of a particular hypothesis that heavy bodies tend to move towards the centre of the earth. Dalton's atoms were essentially the same as those of the seventeenth-century atomists, but Dalton avoided the error of Gassendi, who multiplied his hypothetical atoms so as to explain the perceptions of all the senses by their means. The atomic theory of Dalton completed a process of induction whereby science gained a principle of quantitative correlation. In the same way, the electron entered modern science. Pure abstractions such as the Newtonian mass, space, time and force appear to be insufficient in themselves, and the scientific interpretation of phenomena not capable of treatment by classical mechanics has proceeded with the use of entities which must possess the qualities of hypotheses. This method Huygens, if not Newton, would have supported.

Science is fortunately an activity in which no one need consider whether his methods have the blessings of the patriarchs or not, but it is interesting to see that in this particular respect the Huygensian attitude confers more freedom than the Newtonian and that, in regard to the broad conception of the place of hypotheses, Huygens was a more profound methodologist than Newton. Newton, on the other hand, showed the clearer grasp of the nature of scientific laws as inductions from which the particular event might be deduced. Whether he would have regarded it as the true function of science to build up a colligative system from which, ultimately, laws might be deduced is another matter. Probably it would appear to him, as it does to certain modern critics, to be a repetition of the errors of Cartesianism though in a more scientific—if not less metaphysical—guise.

In the scientific work of the eighteenth and nineteenth centuries the distinction which presents itself before many others is that of the status of mathematical laws. Following Newton's example, some physicists considered that it was undesirable to go beyond the mathematical formulation of laws. Ampère and Cauchy investigated electric forces mathematically on the Newtonian law of inverse squares; in Great Britain Faraday and Clerk Maxwell studied the effect of the intervening medium and tried to picture a mechanism by which electric forces could be transmitted. The former is the Newtonian, the latter the Huygensian method. The same divergence is clear in the treatment of the concepts of energy and entropy. As mathematical quantities they are doubtless valid abstractions; as fictitious entities existing in their own right, they raise questions of their reality which cannot be answered with final agreement except by those who adopt the same metaphysics. To keep science clear of metaphysical entanglements has long been regarded as of the first importance. It is surely in this light that Newton's famous axiom should be remembered.

OBITUARIES

Mr. Arthur Grove

The death of Arthur Grove on February 2, in his seventy-eighth year, removes a noted personality from the ranks of the scientifically minded gardeners. The youngest son of Sir George Grove, editor of the "Dictionary of Music and Musicians" and first director of the Royal College of Music, Arthur Stanley Grove was, like his father, an engineer, but early in his life he became attracted to horticulture, as his father had been to music, and he acquired a remarkable collection of plants in his garden near Henley. Stimulated by H. J. Elwes, Grove became interested in the genus Lilium and made this a lifelong study, but though he specialized on lilies he maintained a very wide interest in gardening and was for many years the chief contributor on horticultural subjects to *The Times*. He had an unusual knowledge of good plants and wrote extensively in the gardening Press.

The success of Grove's horticultural skill should be appraised in the light of virus diseases. He took infinite pains with his lilies and achieved remarkable success, but some species repeatedly failed after a few years. In any lily collection there is virus-infected material from which the most carefully raised seedlings may become affected. Grove was baffled and mystified, but never gave in. He attributed his failures to such factors as soil acidity, or alkalinity, or to Botrytis. This was not surprising since plant pathologists could give him no light. Virus diseases of lilies were, indeed, not generally recognized in Great Britain until some years after Ogilvie's work had been published (1928).

The most important work upon which Grove embarked was the preparation of a Supplement to Elwes's "Monograph of the Genus Lilium", and in this he was able to incorporate the results of his unrivalled experience. He had a profound respect for authority, and as an amateur he hesitated to run counter to the writings of professional botanists. It was partly owing to this fine feeling and partly on account of ill-health that he sought expert help when he came to face the critical and much confused species that had to be described for the later parts of the Supplement.

Grove was elected a fellow of the Linnean Society in 1903. He was awarded the Victoria Medal of Honour of the Royal Horticultural Society in 1924, the Veitch Memorial Gold Medal in 1934, and the Gold Medal of the Massachusetts Horticultural Society in 1936. He was, moreover, the first recipient of the Lyttel Lily Cup. He had an attractive literary style and will always be remembered for his great charm of manner and for his whimsical humour.

A. D. C.

Dr. Edward Bureš and Prof. Stefan Kopeć

It has recently been learned that Dr. Edward Bureš, lecturer in organic chemistry at the Charles University, Prague, until the Germans closed the university, has died. He was arrested soon after the outbreak of war and has presumably died in a German concentration camp.

Dr. Bureš had made several contributions to the study of plant chemistry, having described a number of new sterols, for example, raphanisterol from mustard, alkaloids (nymphæine from water-lily) and glycosides.

Prof. Stefan Kopeć, professor of biology in the University of Warsaw, was killed some months ago by the Germans. He was arrested among the 150 Polish persons, every tenth of whom was shot. They had not committed any offence but were taken as hostages after an unsolved incident in which a German was killed.

We regret to announce the following deaths:

Dr. Frank Conrad, assistant chief engineer of the Westinghouse Electric and Manufacturing Company of Pittsburgh, on December 11, aged sixty-seven years.

Prof. P. H. Hanus, emeritus professor of education in Harvard University, on December 14, aged eighty-six years.

Prof. Simon Isaac, formerly professor of internal diseases in the University of Frankfort, an authority on diabetes.

NEWS and VIEWS

Dr. W. Temple: Archbishop of Canterbury

The King has been pleased to nominate the Right Hon. and Most Rev. William Temple, Lord Archbishop of York, Primate of England and Metropolitan, for election by the Dean and Chapter of Canterbury in the place of the Right Hon. the Most Reverend Cosmo Gordon Lang, Lord Archbishop of Canterbury, Primate of All England and Metropolitan. Dr. Temple, who is sixty years of age, has been Archbishop of York since 1929. He was president of the Oxford University Union in 1904, and afterwards a fellow of Queen's College. He was appointed headmaster of Repton School in 1910, where he stayed four years.

Educationists will welcome this appointment, for Dr. Temple has associated himself with social problems and education for many years. He was president of the Workers' Educational Association from 1908 until 1920, and has thus guided it to the great influential position which it now holds in adult and other educational activities throughout the country. His lectures and addresses, especially to undergraduates and other young people, are always listened to with eager attention. In a sermon during the jubilee celebrations of the Victoria University of Manchester, he especially emphasized the need for greater encouragement of research among the staffs of our universities. He is a philosopher of outstanding merit.

The King has also been pleased to nominate the Right Rev. C. F. Garbett, Lord Bishop of Winchester, for election by the Dean and Chapter of York in the place of Dr. Temple. Dr. Garbett has also shown himself deeply interested in social questions.

Dr. Peter Kapitza, F.R.S.: Faraday Medallist

Dr. Peter Kapitza, director of the Institute for Physical Problems of the Academy of Sciences of the U.S.S.R., has been awarded the Faraday Medal of the Institution of Electrical Engineers, "for his notable contributions to science in the generation and utilization of intense magnetic fields". Dr. Kapitza began his scientific career some twenty years ago in the Cavendish Laboratory, Cambridge, where he succeeded in producing magnetic fields much stronger than had hitherto been obtainable. To avoid the difficulty of the heating up of the coil in which the magnetic field was produced, he used a large power for a very short time only; the time was, however, long enough for most magnetic effects to establish themselves, and Kapitza developed many ingenious devices for studying the magnetic properties of matter in such transient fields. With this powerful technique he cleared up various doubtful points about magnetization at high fields and was able to measure the magnetostriction of diamagnetic substances for the first time; a series of researches on the change of electrical resistance of metals in the new region he had opened up also brought to light many interesting new features.

Since magnetic properties generally become much more marked at low temperatures, Kapitza set about the building of a cryogenic laboratory, and here again he brought to bear that rare combination of the talents of the physicist and the engineer which characterizes so much of his work. His work in Cambridge culminated with the development, in the Royal Society Mond Laboratory, of a new method of liquefying helium using the principle of adiabatic expansion. In 1934 he returned to his native country to set up and direct the new Institute for Physical Problems of the Academy of Sciences of the U.S.S.R., where he has continued both his magnetic and his low temperature researches. Recently he has made important discoveries about the remarkable 'superfluid' properties of liquid helium, and he has also developed a much more economical method of liquefying air. For this latter work, which is of considerable industrial as well as scientific interest, he was awarded the Stalin Prize last year.

Rev. T. E. R. Phillips

The University of Oxford is conferring the degree of D.Sc., *honoris causa*, on the Rev. T. E. R. Phillips on February 28. Mr. Phillips's astronomical work began in 1896, while he was curate at Hendford, near Yeovil, where he started systematic work on the planets, especially Jupiter and Mars. In 1916, he was appointed rector of Headley and he set up an observatory in the rectory glebe, where he added an 18-in. reflector (mirror by With) to his other equipment. Mr. Phillips's work on Jupiter has consisted mainly in investigating the surface currents, and the times of the passage of various surface features across the central meridian of the planet are included in this. Other features to which he gave a considerable amount of attention are a 'circulating current' in the southern hemisphere of the planet, the Red Spot, and the South Tropical Disturbance. He has recorded more than a dozen distinct surface-currents, which are well defined and show minor variations of period; incidentally, it may be mentioned that he obtained some 30,000 spot transits. The 8-in. refractor loaned by the Royal Astronomical Society was used for double-star measurements and also for determining the light-curves of long-period variables. The results of his harmonic analysis of the light-curves of about eighty stars were given in his presidential address to the British Astronomical Association in 1916.

Mr. Phillips has been president of Commission 16 of the International Astronomical Union, specially concerned with the physical study of the planets, president during 1914–16 of the British Astronomical Association, and during 1927–29 president of the Royal Astronomical Society. Mr. Phillips is also a meteorologist, and has kept an unbroken daily record of temperatures and rainfall at Headley for twenty-five years. These results and also the results of his harmonic analysis of a number of annual temperature curves in various parts of the British Isles will be published after the War. He is a keen botanist and is specially interested in British and Alpine flora. He is still continuing to use the observatory at Headley, although he retired from active work in the church a year ago, owing to failing health. His many friends hope that he will be long spared to carry on his scientific work.

Home-grown Timbers

The Forest Products Research Laboratory at Princes Risborough has recently issued a third edition (War Emergency Edition) of the "Handbook of Home Grown Timbers" (H.M. Stationery Office, 1941). This has become necessary owing to the greater demand being made on home resources due to a decrease of imports through the restriction of available shipping and an intensified demand. The edition includes information on a number of timbers not in general use, if not entirely unutilizable in peace-time, which can, it is stated, be satisfactorily employed for various useful purposes under war-time conditions. A notable addition, which the wholesale destruction caused by the German bomber has rendered advisable, is information on the fire-resisting properties of most of the species. These valuable data are the result of extensive experimental work carried out at the Laboratory. British grown timbers, we are told, as can be readily imagined, are now being employed in greater quantities and for very exacting purposes, and users are frequently at a loss to know how a particular species may best be utilized for some specified object for which imported timbers have been used in the past. It would be useful and interesting if a list could be made of the actual purposes throughout the country for which home-grown timbers are now being employed.

Genes, Viruses and Proteins

Vol. 9 of the Symposia on Quantitative Biology, published by the Biological Laboratory, Cold Spring Harbor, Long Island, has just appeared. It covers in about 300,000 words the immediate field of "Genes and Chromosomes" indicated by its title, and also a wider range of recent research which can be related to the study of chromosome structure either technically or theoretically. There are thirty-four papers and discussions dealing with optical observations, including the use of the ultra-violet and electron microscopes, X-ray experiments on cell-activity and chromosome breakage, the theory of protein and nucleic acid structure and behaviour, the chemistry and mutations of viruses and genes, and finally the use of the heavy nitrogen isotope in the study of amino-acid exchanges. The series ends by a summary and review by H. J. Muller. This volume is remarkable not only for almost every contribution being new in detail of technique and observation, but also for the whole point of view having arisen from the converging development of genetics, cytology and chemistry during the last ten years.

Electric Cables

Mr. S. W. Melsom, of the Cable Makers' Association, devoted the greater part of his chairman's address to the Transmission Section of the Institution of Electrical Engineers (*J. Inst. Elect. Eng.*, **89**, Pt. 1, No. 13; 1942) to the subject of cable engineering, first making brief reference to the development of solid plastic materials and proceeding to the question of their application to the manufacture of cables. The fierce light thrown on the older dielectrics by competition from the synthetics has revealed the extraordinarily high qualities of rubber and paper, and in the face of this experience new materials cannot be accepted without the fullest assurance of at least as good service with economic advantage. Although chemists have worked hard on the subject, their products have yet to be proved superior or even equal to vulcanized rubber, but doubtless the apparently parallel paths of the rubber and plastics chemists will ultimately be found to converge, with great benefit to both. The address then dealt briefly with very high voltage cables, research and the much discussed question of standardization, and it was closed with an outline of the standing and responsibilities of the engineer in relation to society, suggesting that it is time the engineer took his fair share in responsibility for the control of affairs, for otherwise the most lucrative profession would be that of reaper and not cultivator, a process which, if carried too far, will choke the life out of any industry or nation permitting it.

Heat Requirements of Buildings

A valuable compendium of information has been issued by the Institution of Heating and Ventilating Engineers in a publication entitled "Recommendations for the Computation of Heat Requirements for Buildings" (Pp. iii+41. 1*s*. 9*d*.) This comprises a section of the guide to current practice which was recently compiled for the use of members, and it places at the disposal of all interested in the subject a most comprehensive collection of data strictly in accordance with present-day practice. The information is conveniently grouped in three parts. That on temperature-rise and rates of change gives the recommended values applicable to buildings ranging alphabetically from aircraft sheds to warehouses. The design of heating and ventilating installations has been, in recent years, greatly influenced by legislation affecting factories, and a special section has been devoted to this class of building. Heat transmittance co-efficients for walls, floors and roofs in a variety of materials constitute the second part, which also includes data as to the allowances to be made for height and for conditions of intermittent heating. The third part deals with conductivity data and the calculation of overall coefficients for composite walls, floors and roofs. Included in it is a table of thermal conductivity and resistivity of practically all the proprietary materials used in building construction. Much of the information given has been obtained from such independent sources as the National Physical Laboratory and the U.S. Bureau of Standards, and for the benefit of those unfamiliar with heat-loss calculations as applied to buildings a typical example is included.

Long-Distance Telephony

Voice-frequency signalling and dialling in long-distance telephony forms the subject of a paper read before the Institution of Electrical Engineers by W. G. Radley and E. P. G. Wright. The paper first sets forth the reasons for modern methods of signalling and dialling over long-distance telephone circuits and for preferring the use of voice-frequency methods for these purposes. An outline is given of the technical problems involved in the design of voice-frequency signalling systems and the author deals with operating requirements as well as with receiver and system design. Reference is also made to the recommendations of the International Consultative Committee on Long-Distance Telephony regarding means of avoiding interference between different signalling systems on international connexions and a forecast is given of the future development of signalling and dialling over long-distance telephone circuits. An interesting table is included which compares the various long-distance signalling systems in great detail.

The Yellow Fever Situation

According to the *Journal of the American Medical Association* of January 10, owing to perfection of control methods initiated by Gorgas and Oswaldo

Cruz, there have been no reports of yellow fever in Brazil or in the whole western hemisphere during 1941 or in the previous three years. Attention now centres on jungle yellow fever, which differs from urban yellow fever in that it is not transmitted by *Aedes œgypti.* Risk of yellow fever, however, will remain so long as the jungle type persists. It is no longer enough to accept clinical opinion, however experienced, for the diagnosis of yellow fever, but laboratory information by viscerotomy and protection tests is necessary. Vaccination has been carried out on a large scale with satisfactory results. The International Health Board of the Rockefeller Foundation continues to co-operate in the epidemiological and laboratory studies of the disease and in the preparation of vaccine.

Seismology in the South-western Pacific

During the past year, 1941, a new teleseismic station was established at Auckland, New Zealand. The station is equipped with a Milne-Shaw seismograph, and accurate time is maintained on the records. It is administered by the Dominion Observatory, Wellington (acting director, Mr. R. C. Hayes), as part of the New Zealand seismological service. The instrument was established with the co-operation of the Auckland Institute and Museum, and is operated by members of the Museum staff. This new station is proving of great value in the recording of earthquakes, not only in the New Zealand region, but also in the south-western Pacific generally.

Rockefeller Medical Studentships

The Rockefeller Foundation is again offering twenty-five studentships to enable men or women to take part of their clinical courses at medical schools in the United States and Canada. The offer is made primarily to help students in schools which have suffered in consequence of enemy action, but suitable applications from all medical schools in England, Wales, Scotland and Northern Ireland will be welcomed. The studentships, which are tenable for two years, will cover all tuition fees, maintenance, etc., but not the cost of travel to and from America. Students must return to Great Britain in order to take their final examination. Application forms may be obtained from the Dean of the Medical Faculty or School and must be sent in only by the Dean not later than April 25.

Journal of the Franklin Institute

In spite of the difficulties of Atlantic transport, copies of the principal American scientific journals continue to reach us. The *Journal of the Franklin Institute* is outstanding from those of general interest and the December 1941 number, including the index to Vol. 232, maintains the usual high standard and variety of interest. A paper by Carl van Doren on Franklin himself deals with the remarkable American after whom the Institute is named. His qualities as man of science, diplomatist, statesman, business man, economist, printer, humorist and wit, writer and sage are all surveyed. Two technical papers are followed by notes from the National Bureau of Standards and the Biochemical Research Foundation, and a lively group of notes on current topics and book reviews. The *Journal* is published monthly from the Franklin Institute in Philadelphia.

Night Sky in March

The length of day and night will reach equality when the sun enters the vernal equinox on March 21d. 6h. U.T. The moon is full on March 3d. 0h. 20m. and on March 2–3 there will be a total eclipse of the moon, visible at Greenwich. The circumstances of the eclipse are as follows:

Moon enters penumbra ...	March	2d.	21h.	27·6m.
,, ,, umbra		2	22	31·3
Total eclipse begins		2	23	33·2
Middle of eclipse		3	00	21·5
Total eclipse ends		3	01	09·8
Moon leaves umbra		3	02	11·5
Moon leaves penumbra ...		3	03	15·0

The moon is new on March 16d. 23h. 50m. and there will be a partial eclipse of the sun on March 16–17, invisible at Greenwich, visible only in the South Pacific and Antarctic Oceans.

The occultations of the planets by the moon are as follows: Venus on March 13d. 15h., Venus 2° N.; Mercury on March 14d. 22h., Mercury 3° S.; Saturn on March 21d. 15h., Saturn 3° N.; Mars on March 22d. 20h., Mars 7° N.; Jupiter on March 23d. 08h., Jupiter 5° N.; Mars and Neptune will be in conjunction on March 2d. 7h., Mars being 1·6° N. Mars, Jupiter and Saturn are well placed for observation during the month. Venus is a morning star, and in the middle of the month rises at 4h. 30m. Among the occultations of stars not fainter than mag. 4, the following may be noted: March 4d. 1h. 22·2m., β Virginis; March 22d. 18h. 41·3m., θ^1 Tauri; March 22d. 18h. 47·8m., θ^2 Tauri.

Announcements

Lieut.-General A. G. L. McNaughton has been elected an honorary member of the Institution of Electrical Engineers. This distinction has been conferred upon General McNaughton, who was until recently commander of Canadian troops in Great Britain, in appreciation of the outstanding services rendered by him to promote the practical application of science to industry, in which respect his work on high-voltage research during his presidency of the Canadian National Research Council has been specially notable.

Colonel S. J. Thompson, governing director of Messrs. John Thompson, Ltd., Wolverhampton (water tube boilers, motor frame pressings, etc.), has been elected president of the Institution of Mechanical Engineers, in succession to Mr. W. A. Stanier, chief mechanical engineer of the London Midland and Scottish Railway, whose term of office has expired.

John Scott Medals and Premiums of the American Philosophical Society have been awarded to Major Edwin H. Armstrong, professor of electrical engineering, Columbia University, for his work in frequency modulation in radio; and Robert R. Williams, chemical director, Bell Telephone Laboratories, for his work on thiamin (vitamin B_1).

Arrangements have been completed for the publication of a volume of "Essays in Anthropology" to be presented to Rai Bahadur Sarat Chandra Roy, the distinguished Indian worker in this field. A limited edition is being printed. Orders for copies, with remittance (*Rs.* 12), should be sent to Dr. D. N. Majumdar, Anthropology Laboratory, University of Lucknow.

Neutralization of Sulphonamide Inhibition of Yeast Growth by *p*-Aminobenzoic Acid

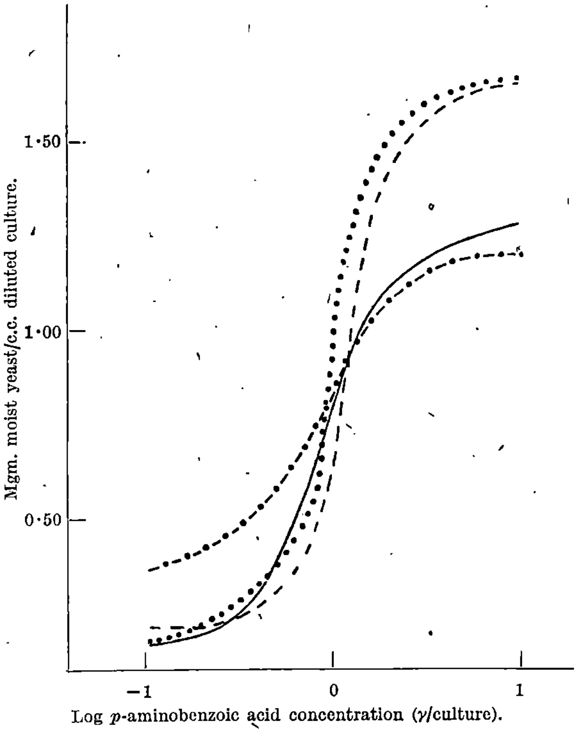
From the many theories concerning the mode of action of sulphonamides, one by Fildes[1] has recently emerged which, because of the volume of evidence brought forth in its support, is now considered the most logical explanation of sulphonamide bacteriostasis. Fildes has suggested that inhibitors of microbial growth are effective as a result of interference with an "essential metabolite", a substance which he defined as having an essential part in the chain of synthesis necessary for growth. Woods[2] was able to show that *p*-aminobenzoic acid nullified the growth-inhibitory action of sulphanilamide for a number of bacteria. Studies in this laboratory[3] have confirmed Woods's original observations. It was found that the *in vitro* bacteriostatic effect of sulphanilamide, sulphapyridine, and sulphathiazole on streptococci, pneumococci, and staphylococci respectively was neutralized by *p*-aminobenzoic acid. Dimond[4] has recently reported similar growth-inhibition of the fungus *Trichophyton purpureum* by sulphanilamide and neutralization of this inhibition by *p*-aminobenzoic acid. The present report describes the application of Woods's findings to yeast growth and suggests the importance of *p*-aminobenzoic acid in yeast metabolism.

The test organism, *Saccharomyces cerevisiæ* No. 139, was cultured in the synthetic basal medium of Snell, Eakin and Williams[5], made complete by the addition of sufficient biotin to support half-maximum growth. The complete basal medium in 10 c.c. quantities was inoculated with 0·06 mgm. moist yeast, and incubated for sixteen hours at 30° C. Growth was measured with a photo-electric nephelometer.

The inhibitory effect of sulphanilamide, sulphapyridine, sulphaguanidine and sulphathiazole was determined by adding the sulphonamide under test to flasks of inoculated medium and incubating as above. Complete inhibition of yeast growth was obtained with the following amounts of sulphonamides: sulphanilamide, 2·0 mgm.; sulphapyridine (sodium salt), 2·5 mgm.; sulphaguanidine, 2·0 mgm.; sulphathiazole, 1 mgm.

The neutralizing effect of *p*-aminobenzoic acid on yeast growth inhibition was demonstrated by the addition of varying amounts of *p*-aminobenzoic acid to flasks of inoculated media, each containing that amount of sulphonamide necessary for complete inhibition of growth. The results are illustrated in the accompanying figure, in which the quantity of yeast growth, plotted against *p*-aminobenzoic acid, was, in general, similar for all the sulphonamides tested. In all cases, the variation of *p*-aminobenzoic acid concentration from 0·1 to 10·0 micrograms per culture resulted in complete range of neutralization.

Since the basal medium used in these experiments was synthetic in composition and did not contain *p*-aminobenzoic acid, it was of interest to determine whether or not this substance was synthesized. A sixteen-hour culture in the complete basal medium as described above was autoclaved to effect hydrolysis and centrifuged to remove cellular debris. The supernatant was assayed for *p*-aminobenzoic acid content by comparing its neutralizing effect on sulphathiazole with that of a reference standard set of *p*-aminobenzoic acid dilutions. It was found that such supernatants contained a substance which neutralized the inhibitory effect of sulphathiazole. When measured in this way, 10-c.c. cultures contained a neutralizing substance equivalent to approximately 1·5 micrograms of *p*-aminobenzoic acid.



NEUTRALIZATION OF SULPHONAMIDE INHIBITION OF YEAST GROWTH BY *p*-AMINOBENZOIC ACID.

— · — · —, sulphapyridine (Na), 2·5 mgm./culture.
· · · · · ·, sulphaguanidine, 2·0 mgm./culture.
— — — —, sulphanilamide, 2·0 mgm./culture.
————, sulphathiazole, 1·0 mgm./culture.

On the basis of the foregoing evidence, the following conclusions seem warranted:

Yeast growth is completely inhibited by sulphonamides. This inhibition is neutralized by *p*-aminobenzoic acid.

Yeast synthesizes either *p*-aminobenzoic acid or its biologically active equivalent. *p*-Aminobenzoic acid may, therefore, be important in yeast metabolism, possibly as the "essential metabolite" of Fildes.

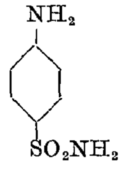
Relative Acidity and Basicity of Sulphanilamide and *p*-Aminobenzoic Acid

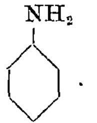
SINCE no determination of the relative acidic or basic dissociation constants of sulphanilamide appears to have been published, this drug was potentiometrically titrated against *N*/1 hydrochloric acid followed by *N*/1 sodium hydroxide. *p*-Aminobenzoic acid and *p*-aminophenylacetic acid were treated similarly for purposes of comparison. In each case, a solution of freshly recrystallized, pure material (0·0005 gm. mol. in 20 ml. of water) was titrated in a beaker fitted with a stirrer, glass electrode and potassium chloride agar bridge connected to a calomel half-cell and a Leeds and Northrup universal *p*H potentiometer assembly. The results are shown in the accompanying figure and the derived (uncorrected) dissociation constants are given in the table.

Substance	*K* (base)	*K* (acid)
Sulphanilamide	$1 \cdot 6 \times 10^{-12}$	$6 \cdot 3 \times 10^{-11}$
p-Aminobenzoic acid	$3 \cdot 1 \times 10^{-12}$	$1 \cdot 5 \times 10^{-5}$
p-Aminophenylacetic acid ...	$3 \cdot 1 \times 10^{-11}$	$6 \cdot 3 \times 10^{-6}$

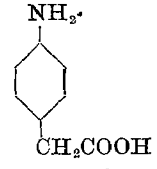
Woods[1] showed *in vitro* that *p*-aminobenzoic acid can counteract the antibacterial action of sulphanilamide; Selbie[2] found that *p*-aminobenzoic acid inhibited the curative action of sulphanilamide in the streptococcal infection of mice; Findlay[3] found that *p*-aminobenzoic acid interfered with the curative action of sulphanilamide on mice infected with the virus of lymphogranuloma; Rubbo and Gillespie[4] first showed that *p*-aminobenzoic acid was a growth factor for a bacterium (*Clostridium acetobutylicum* (W.)) and that its activity could be neutralized by a large excess of sulphanilamide; finally, Lipmann[5] reported that sulphanilamide inhibited the oxidation of *p*-aminobenzoic acid by peroxidase and hydrogen peroxide. There is thus good support for Fildes's hypothesis[6] that sulphanilamide acts biologically by competing against the essential metabolite, *p*-aminobenzoic acid, for the possession of particular groups (receptors) in enzyme systems. Fildes further states that such an inhibitor as sulphanilamide requires sufficient chemical similarity to the essential metabolite in order to fit the same enzyme system and yet must differ sufficiently to be devoid of metabolic activity.



Sulphanilamide

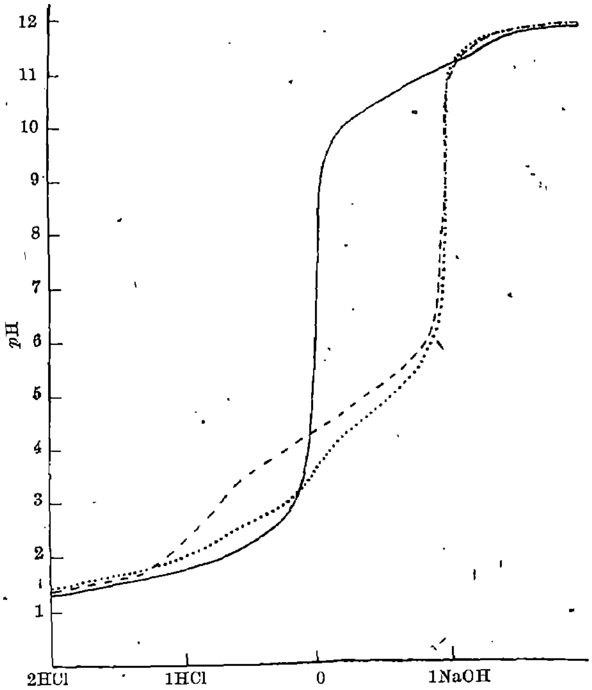


p-Aminobenzoic acid



p-Aminophenyl-acetic acid

Sulphanilamide answers to this description since, as the above formulæ show, it has a certain steric similarity to *p*-aminobenzoic acid and resembles it in forming salts with strong acids and strong bases. As a result of the potentiometric titrations, this comparison can now be put on a more quantitative basis. Sulphanilamide and *p*-aminobenzoic acid are found to be bases of approximately the same strength, but sulphanilamide is about a million times weaker as an acid. This weak acidity of sulphanilamide is probably unessential as is shown by the high efficiency of 4 : 4′-diaminodiphenylsulphone. On the other hand, the basicity seems highly significant, being common to both substances. The biological importance of such a feeble basicity (K base $= 10^{-12}$) may be connected with chemical reactions other than salt formation, possibly with the formation of hydroxylamino compounds. At least, it is known that stronger, simple aromatic bases such as aniline (200 times) and *p*-aminophenol (2,000 times stronger than sulphanilamide) do not possess sulphanilamide-like activity.



POTENTIOMETRIC TITRATION CURVES AT 20° C.
...... *p*-aminobenzoic acid;
—— sulphanilamide;
- - - *p*-aminophenylacetic acid.

p-Aminophenylacetic acid was included in these titrations since Rubbo *et al.*[7] showed that it is ten times as potent a growth factor for *Cl. acetobutylicum* (W.) as *p*-aminobenzoic acid and, unlike the latter, possesses no anti-sulphanilamide activity[8]. The titrations show that both growth factors have approximately the same strength as acids, but *p*-aminophenylacetic acid is ten times as strong a base. While it would be premature to draw conclusions from these results, the further study of growth-factor chemistry along these lines seems indicated.

Genetic Nature of Self- and Cross-Incompatibility in Potatoes*

INVESTIGATIONS on the various types of sterility in potatoes were begun in 1936 and in the present note the genetic nature of sterility resulting from physiological incompatibility is reported.

Although a great amount of work on self- and cross-incompatibility has been done in a variety of crops, very little information on the subject is available on potatoes. Stout and Clark[1] and Clark[2] mention the occurrence of self- and cross-incompatibility in two species, *Solanum chacoense* and *S. Jamesii*.

Our investigations reveal that many of the diploid ($2n = 24$) species, including *S. aracc-papa*, *S. Caldasii*, *S. chacoense*, *S. Jamesii* and *S. subtilius*, are characterized by a high degree of physiological self-incompatibility while several tetraploid ($2n = 48$) species and the hexaploid ($2n = 72$) species *S. demissum* are self-compatible.

The genetic nature of self- and cross-incompatibility has been worked out for *S. Caldasii* and *S. subtilius*.

S. Caldasii : Sixteen varieties of this species were intercrossed in all possible combinations. These gave five intra-sterile but inter-fertile classes with 1, 2, 4, 4 and 5 varieties in each of the classes respectively.

S. subtilius : Only one variety was available. This was cross-compatible with all the five classes mentioned above and therefore represented the sixth class.

Four families derived from crosses between representative plants of the six groups mentioned above were raised, and plants in each family inter-crossed among themselves and analysed for the existence of intra-sterile and inter-fertile groups.

1. Family No. C–77—*S. subtilius* var. V_1 × *S. Caldasii* var. M_{05}.

Twenty-two plants when inter-crossed gave two (*A* and *B*) inter-fertile but intra-sterile classes. The male parent associated itself with group *A* while the female parent (group *C*) was cross-compatible with both the groups.

2. Family No. D–27—*S. Caldasii* var. 012 × *S. Caldasii* var. 07.

Seventeen plants when inter-crossed gave results similar to those obtained in cross No. 1. Class *E* included the male parent while class *F*, the female parent, was cross-compatible with both *D* and *E* classes.

3. Family No. D–25—*S. Caldasii* var. 04 × *S. Caldasii* var. 01.

Twenty-two plants when inter-crossed gave four almost equal-sized intra-sterile but inter-fertile groups. Both *K* and *L*, the male and female parents respectively, were cross-compatible with all the four groups, *G*, *H*, *I* and *J*.

4. Family No. *D*–26—*S. Caldasii* var. 07 × *S. Caldasii* var. 01.

The behaviour of this cross was similar to cross No. 3. The four intra-sterile inter-fertile groups, *M*, *O* and *P* were compatible with the two parental groups *Q* and *R*.

The four crosses above gave in all eighteen groups of plants, represented by the letters *A* to *R*. Examination of the data showed that certain groups contained genotypically similar plants with regard to self-sterility factors. To confirm this conclusion and to determine the major groups, two plants from each of the eighteen groups were selected and the thirty-six plants were inter-crossed in all possible combinations. The results so obtained are given in the accompanying diagram, which clearly brings out the relationship between the various groups. The two plants under each group behaved similarly with regard to compatibility relationship. The eighteen original groups of plants, it will be seen, are composed of only eight major groups.

The results outlined above show that self- and cross-incompatibility in *S. Caldasii* and *S. subtilius* are distinctly inherited characters.

DIAGRAM SHOWING THE RELATIONSHIP OF THE EIGHTEEN INTRA-STERILE GROUPS.

—, cross- and self-incompatible combination; +, cross-compatible combination.

Detailed examination of the data available shows that there are at least five sterility factors S^1, S^2, S^3, S^4 and S^5 which, operating in various combinations, determine self- and cross-compatibility. The genetic composition of the eight major groups of plants shown in the diagram has been established and is given in the diagram. The mode of action of these factors is in conformity with the oppositional factor hypothesis developed by East and Mangelsdorf[3]. Here it is of interest to note that the five '*S*' factors can give only ten possible combinations out of which eight have been established, and the representative plants are being maintained as 'testers' for further work. Suitable crosses have been made to secure the remaining two combinations, S^3S^4 and S^3S^5.

There is evidence of a sixth '*S*' factor, but the data so far available are not sufficient to establish its existence positively. Some varieties of *S. chacoense* appear to possess in addition to '*S*' factors a fertility factor '*F*'. Investigations in these directions are in progress.

It may be pointed out here that *S. subtilius* and *S. Caldasii*, which resemble each other closely in their floral and vegetative characters and in their reactions to short-day conditions, also possess '*S*' factors in the same allelic series. Therefore there does not appear to be any reason to regard them as separate species.

The investigation reported above forms part of the work of the Potato Breeding Scheme for Northern India financed by the Imperial Council of Agricultural Research the assistance of which is gratefully

Colour Measurement

Messrs. Smith, Guild and Donaldson's fears[1] of misconceptions were not at all justified. My letter[2] directed attention to certain *general* aspects of the physics of colour measurement. Emphasis was upon the need for knowledge in order to provide, for the concretest possible colour problems, the fullest possible analysis. Technical developments were a secondary consideration. I have not committed the elementary errors (*a*) of confusing the C.I.E. standards with the procedure, or (*b*) of thinking that errors in $\chi_{\text{C.I.E.}}$ values are possible owing to the procedure followed in the original experiments. The C.I.E. standards as such are exact. Also, I have no difficulties with the C.I.E. standard observer. All my references to the C.I.E. colorimetric system involved purely its place in a general physics of colour. The C.I.E. system of colorimetric standards, physical constants and agreed procedure is a convention which I do not regard as open to question, or as involved radically in this discussion. I do not question Messrs. Smith, Guild and Donaldson's appraisement of the merits of the C.I.E. system and have expressed parallel sentiments recently[3].

It would appear that Messrs. Smith, Guild and Donaldson hold the C.I.E. system to be capable of fulfilling the conditions of physical measurement for any field size, field brightness, etc. With this I cannot agree. The original measurements of Guild and Wright only provide evidence for the use of the C.I.E. system in the conditions under which such measurements were obtained. Ives[4], in referring to this same question of validity in relation to field size, brightness and the "visibility function", which is a very essential part of the C.I.E. data, says: "The International Illumination Commission in adopting a certain luminosity curve for the equal energy spectrum has in effect committed itself to the photometric conditions under which this curve was made and holds . . . and has authorised the use of a small photometric field." Guild[5], after the institution of the C.I.E. colorimetric system, has stated "that the colour-matching relations of stimuli can be expressed quantitatively in terms of two independent variables" [for example, x and y, in $x+y+z=1$] "has to be qualified by restricting it to a range of conditions within which the visibility curve is known to be constant.". This clearly is an application of the fact that, although a convention may be created at will, its physical validity is limited to the range of conditions within which it is known to apply. Its present bearing is obvious.

That on passing from foveal to peripheral vision matches of colour vary is clearly stated by Abney[6], Hering[7], von Helmholtz[8] and others. Such differences as these are not to be ascribed merely to peculiarities distinguishing the properties of the observer from a statistical average, as might be concluded from the letter of Messrs. Smith, Guild and Donaldson, but to common differences between the colorimetric properties of foveal and extra-foveal vision. Some consequences of this have in fact been described by Dr. Guild[9] in the words: "A large photometric field which averages the properties of a large region of the retina will in general give greater weight to radiation of shorter wavelength than a smaller field not extending so far beyond the fovea." This effect, which may be considerable, may readily be demonstrated and probably accounts for the phenomenon, described by Harrison[10], having an important practical bearing, namely, that a standard white equal in brightness to a comparatively bluish white when viewed by foveal vision, appears less bright than the same bluish white when viewed with a large photometric field. Thus, the essential condition to be complied with by a physical measurement, namely, that it shall correlate physical quantities with magnitudes in serial order, and not assign two magnitudes to the same quantity, or vice versa, is not necessarily still complied with by the C.I.E. system when the field size is extended. The adaptation of the C.I.E. colorimetric system to large fields is therefore only possible by virtue of a convention embodying some arbitrary and artificial restriction.

Let me say, apropos of Messrs. Smith, Guild and Donaldson's reference to the large colorimetric field used with a spectrophotometric match, as a technical device to aid C.I.E. colour measurement, that I intend these remarks to be no criticism of the use of this, provided only that proper qualifications as to validity are accepted; but it may be as well to point out that the spectrophotometric restriction, which is implied in their reference in this connexion to a "physically uniform field", reduces Newton's law, upon which colorimetry is based, to a tautology, and destroys its essential independence of spectrophotometric distribution. Even in such circumstances, that is, with a physically uniform field, differences in appearance in different parts of the field will sometimes be perceived, as when, for example, the radiation comprises two spectrum bands (their half-width may be at least 500 A.) centred approximately about wave-lengths 0·49 μ and 0·62 μ. In this case, although the major part of the field appears white, the central region of the field of vision appears pink, due to the effect of the macula lutea. In ordinary circumstances, vision synthesizes the whole impression received, into a visually homogeneous complex corresponding[2] to χ_N. That "regional variation of retinal properties is formally irrelevant to appearances in an extended field", as stated by Messrs. Smith, Guild and Donaldson, results in such cases in two differing appearances having simultaneously the same colorimetric specification. It is clear, however, that when conditions are not restricted to the sphere of significance of the quantities measured, "we can obtain a colour and brightness match under any conditions whatever and reduce the results to the *form* of a colorimetric relation without realising that the figures so obtained are meaningless"[5]. It will be clear from the foregoing that for conventional measurement to be physical measurement it must follow the *ABC* of physical science, namely, (*A*) experiment, (*B*) hypothesis, (*C*) verification, (*D*) standardization and measurement.

The statements of Messrs. Smith, Guild and Donaldson concerning accuracy may be accounted for by my statements being understood too narrowly, as applying to the C.I.E. system, instead of to the physics of the subject. Other points arise from Messrs. Smith, Guild and Donaldson's letter, which cannot be considered here out of considerations of space, but I hope it will be perceived that there remains material for investigation and grounds for new and broader conceptions in this subject.

The Electromagnetic Mental Picture

RECENT text-books[1] reflect a certain uneasiness concerning the presentation to students of 'engineering' electricity. Some teachers advocate classical field theory alone, others introduce the electron theory, linking it with field theory at every stage. But the awkward unsolved problems of theory cannot then be avoided; thus, the two writers cited take quite different views concerning the induction of a current by motion of conductor and magnet respectively. These theoretical problems do not concern the designer and inventor, who needs above all a mental picture which will give a correct qualitative prediction of the functioning of any proposed apparatus. The formulæ which he will then apply for calculation may, as we know, be derived from various quite different hypotheses. Such differences as appear capable of deciding between different hypotheses are beyond the limits of error of our experimental powers[2].

Useful as the field picture undoubtedly is, the literature from the time of Faraday to the present day affords numerous examples of futile experiments and discussions based upon a too literal interpretation of it. Anyone can test the fact that it may mislead the most experienced. I have asked more than a dozen highly skilled physicists and radio research men whether the inductance of a straight wire is greater or less than that of the same wire bent into a circle. Without exception they answered wrongly. The only correct answer so far came from a young chemist. In the following cases the field picture as usually stated seems to be inadequate. If a toroid solenoid is placed with its plane at right angles to that of a horseshoe magnet and with a few of its turns in the pole gap of the magnet, the field picture seems to call for a torque on the toroid, but none on the magnet. Again, if a horseshoe magnet be rotated when placed so as to send flux through a few turns only of a short-circuited toroid, the field theory seems to call for an alternating current in the toroid, with no reactive torque on the magnet. It is interesting to consider also the effect of removing to a distance that part of the toroid which is *outside* the field of the magnet.

Radio is now perhaps the most important, and certainly the most progressive branch of electrical engineering, and here the particle picture is essential in vacuum tube discussion. Why not base the consideration of capacity, inductance and transmission upon it as well? Historical piety should not lead us to burden the beginner's mind with the difficulties and artificialities of the magnetic field picture, evidenced in the treatment of open and frame aerials, or of the fields near a transmitting antenna. If radio phenomena are dealt with on the lines given in my letter of August 16, 1941, the resulting mental picture of phenomena is at east as penetrating and illuminating as that given by field theory.

Occurrence of Ctenodrilus in the Pacific

THE annelid Ctenodrilus does not seem to have been recorded outside Europe, so that its occurrence in quantity at Ladysmith Harbour, on the east coast of Vancouver Island, B.C., is perhaps worthy of note. A small artificial lagoon was constructed there last summer in connexion with work on oyster culture in which the temperature of the water rose abnormally high. Material, collected with a towed plankton net in this lagoon in August contained large numbers of *Ctenodrilus serratus* (O. Schmidt) which has probably been swept off the eel-grass and other vegetation growing there.

Ctenodrilus is of some special interest because divergent views have been held from time to time as to its taxonomic position. It is now generally regarded as a polychæte and placed among the Cirratulidæ.

British Zoologist Prisoners of War in Europe

A FELLOW of this Society resident in a country at present under German control has generously offered to help British zoologists and entomologists who are prisoners of war in Germany or the enemy-occupied countries of Europe by correspondence and the loan of literature and such other means as are within his power.

The Royal Entomological Society of London is in regular communication with this fellow and invites information regarding zoologists and entomologists known to be prisoners of war in Europe. Exact details of name and address are the only essentials required, and it is emphasized that the Society has no means of transmitting messages to prisoners except through the service organized by the British Red Cross. Information may be sent to the Registrar, Royal Entomological Society of London, 41 Queen's Gate, London, S.W.7.

FRANCIS J. GRIFFIN
(Registrar).

RESEARCH ITEMS

Morphology of a Cicada

J. W. EVANS has recently described the structure of the anomalous cicada *Tettigarcta* White. Little has been known of this insect, which betrays certain primitive features and is widely divergent from all other Cicadidæ (*Papers and Proc. Roy. Soc. Tasmania* for 1940; pub. 1941). Most of the specimens of the species *T. tomentosa* were taken at an altitude of 2,500 ft. during the Tasmanian winter (May and June), being attracted to lights at night. During the day the insect shelters beneath bark. Among various features the absence of tympanal organs in both sexes is notable. Tymbals, however, are present with their muscles slightly less developed in the female than in the male. It is conjectured that Tettigarcta is a descendant from an early cicadan stock that possessed well-developed sound-producing organs and sound-detecting organs in both sexes. For some reason, possibly associated with its nocturnal habits and cold environment, for other cicadas are essentially scent-loving insects, it has ceased to produce sound. Among other structural features the nymphs of Tettigarcta have nine segments to the antennæ—a higher number than is found in other cicadas. The venation is exceptionally complete with a separate costal vein in the hind wing. The male genitalia have a true ædeagus, also there is an unusual development of the basal plates, and harpagones are present.

Origins of Garden Roses

THE continuous blooming of garden roses must be a matter of wonder to those who compare it with the limited flowering of wild types. C. C. Hurst shows (*J. Roy. Hort. Soc.*, 66, Pts. 7 and 8, July and August, 1941) that this fortunate gene was introduced early in the nineteenth century from the China rose, *Rosa Chinensis*. It was first crossed with the Tea rose, *R. gigantea*, to form pink, blush and yellow stocks. The Pink China crossed with *R. moschata* gave the Noisette rose and when separately combined with the Pink Autumn Damask, *R. rubra*, it gave the Bourbon Rose. Hybrid Perpetuals were obtained by crossing hybrid China forms with Bourbons, Noisettes, and an English stock named after the Duchess of Portland. Hybrid Tea roses, occupying the throne of garden beauty, resulted from a fusion of Hybrid Perpetuals and Teas. The twentieth century brought the introduction of *R. lutea* from Persia, and with it the Pernet rose (Hybrid Perpetual × Austrian Briar, *R. lutea*). A wealth of historical detail is combined with genetical information in the papers under review.

A New Strain of Potato Virus

SINCE the discovery that interveinal mosaic and crinkle virus diseases of the potato are caused by mixtures of viruses, much work has been devoted to the isolation and identification of the constituents. Phyllis M. Clinch has recently elucidated one of the remaining problems (*Sci. Proc. Roy. Dub. Soc.*, 22, No. 46, 435–45, December, 1941). One source of interveinal mosaic, which is a mixture of viruses X and F, was found to include also a strain of top-necrosis. Removal of the X virus from this complex left a dual virus which is responsible for virulent tuber blotch, and also produces streak symptoms in the foliage. This has been found to be identical with a potato 'streak' the symptoms of which were described earlier by Koch and Johnson, and thus is now shown to be caused by a mixture of top-necrosis and F viruses.

A Genus of the Discomycetes

A MONOGRAPH of the Discomycete genus Rutstrœmia has recently been published by W. Lawrence White (*Lloydia*, 4, No. 3, 153, September, 1941). There is no modern handbook to the genera and species of the Discomycetes, and any critical study like the present monograph is a welcome contribution. The genus Rutstrœmia was originally established by Karsten, and has been revived to include many of the inoperculate Discomycetes at present scattered through the current genera Helotium, Phialea, Ciboria, Sclerotinia and Cyathicula. Forty-one species are described critically, and the material has been obtained from as many countries as present world conditions allow. A key to the American species is given, and seventy-five half-tone figures elucidate the text.

Physiological Genetics of Neurospora

G. W. Beadle and E. L. Tatum (*Proc. Nat. Acad. Sci.*, 27, 499–506; 1941) describe useful methods for the analysis of gene action in biochemical phenomena. They irradiate the fungus Neurospora with X-rays and grow the resulting strains from single-spore culture on a medium containing as many of the synthesized products as possible. They also grow these spore strains on media containing only the primary ingredients. A normal strain is able to synthesize vitamin B_6, etc., from this latter medium, but a mutant strain may not survive through its inability to do so. By adding vitamin B_6 to such a medium, they can restore the growth-rate of the mutant strain to that of the normal strains. Out of two thousand single-spore cultures analysed, one was found to be pyridoxinless (unable to synthesize vitamin B_6), another failed to synthesize *p*-amino-benzoic acid, a further one could not synthesize thiazole. All these mutants differ from normal by one gene differences. The physiological methods of analysis which are used will enable the steps in synthesis to be studied in relation to gene changes.

Evolution of Continents

IN the Bruce-Preller lecture for 1941 Sir Thomas Holland discusses the data bearing on the highly controversial subject of continental drift, and makes suggestions towards a possible reconciliation of the conflicting evidence (*Proc. Roy. Soc. Edin.*, B, 61, II (13), 149; 1941). He directs attention to various geological lines of evidence "which cannot, so far as anyone knows, be explained in any way except by continental drift". The most formidable among these is the record of Upper Palæozoic glaciation on each of the now scattered continents of Gondwanaland. On the other hand, there is the geophysical difficulty of finding an adequate motive force for continental drift, if the view that the earth is solid and strong down to about half its radius be accepted as a scientific fact. Holland points to one obvious direction in which we may look hopefully for a clue to the reason for this apparent inconsistency: "the evidences for continental drift all belong to a relatively distant past", whereas "the seismic records . . . indicate the state of the Earth's interior to-day". He suggests that so long as geophysicists give good reasons for denying the physical possibility of continental drift, there are only two courses open: (i) to reconsider the possibility that some of the geological revolutions in the past were on a scale large enough to put the evidence of present-day conditions out of court; and (ii) to continue with the "prosaic task of accumulating more cold facts". The second of these is the more essential because by no means all geophysicists deny the physical possibility of continental drift. In this connexion reference may be made to the following papers: D. Griggs, *Amer. J. Sci.*, 237, 611; 1939; and B. Gutenberg, *Trans. Amer. Geophys. Union*, 556–58 (1941).

Activation of Nitrogen in the Silent Electric Discharge

S. S. Joshi and A. Purushotham, of Benares Hindu University, describe, in a communication to NATURE, dated November 17, 1941, some work on the formation of active nitrogen in a Siemens' ozonizer. Both alternating and unidirectional potentials were used. The walls of the ozonizer were suitably coated, and an idle volume was connected in series with the exhaust end of the ozonizer and the pump to act as a gas reservoir. With careful adjustment of the applied field and gas flow to suit the gas pressure, activation of nitrogen in the *silent discharge* was observed up to a pressure of 150 mm. mercury, using soft and pyrex glass tubes. By raising the frequency of the A.C. supply, both the yield and the maximum pressure could be increased appreciably; to do this it was necessary to use ozonizer tubes made of materials, such as silica, of high dielectric strength in order to withstand more intense fields; the walls were silvered. Apart, perhaps, from 'controlled electron' sources (Caress and Rideal, *Proc. Roy. Soc.*, A, 115, 684; 1927), with which the yield of active nitrogen was limited by the low pressure, the *silent discharge* was found to be the simplest in technique and most suitable for determining the electrical quantities characteristic of the reaction under given conditions. With the frequency n, the gas pressure p, and the temperature T kept constant, it was found (Joshi, *Current Science*, 8, 548; 1939) that as the applied potential was progressively increased, activation of the gas to produce a just perceptible afterglow set in at a critical potential V_m characterized by a sudden increase in both the electric current and the energy dissipated in the system. With constant n and T the critical potential increased sensibly linearly with p, the increase being pronounced at lower frequencies; at constant p and T the critical potential diminished with increasing n in the range 50–500 cycles per sec. Changes in V_m produced by admixture of a foreign gas or 'impurity' serve markedly to reveal its influence as a catalyst or otherwise in the activation of nitrogen. V_m resembles the corresponding Paschen potential. It is considered that ionization of nitrogen in one or more stages is a chief determinant of changes that precede its activation.

Laboratory Test for Preservation of Iron by Paint

To determine how well a paint protects a metal surface against corrosion, plaques covered with it are usually exposed outdoors. A laboratory test has recently been developed which shortens the weathering time to hours and does not destroy the film. The test, the technique of which is described by R. B. Gibney (*Bell Lab. Rec.*, 20, No. 2, Oct., 1941), gives evidence as to how well a paint protects metal, but little information on the weathering of the paint itself. In the presence of water, metallic corrosion results from the electrochemical action between small adjacent surface areas, potential differences being set up between them. The potential of the whole surface is that of all the small areas involved, and can be measured with reference to a standard electrode. The extent of corrosion can be determined by recording continuously the potential changes of the metal over a few hours. Surface areas of a corroding metal are of two kinds: anodic (or electronegative), where the metal goes into solution, and cathodic (or electropositive) where hydrogen is evolved. If the metal corrodes freely the cathodic areas tend to become 'clogged' with hydrogen and the resultant potential of the plate becomes more electronegative. This effect is strongly accentuated when oxygen is excluded. If the metal does not corrode it is because the anodic areas become insulated with an extremely thin film of corrosion products, the potential of the plate being nearly that of the cathodic areas. Thus the potential of a corroding metal becomes more electronegative with time, while that of a non-corroding metal becomes and remains electropositive, and this is the basis for the rapid determination of the behaviour of painted iron.

Components of Fehling's Solution

IN a paper read before the Society of Public Analysts and Other Analytical Chemists on February 4, J. G. N. Gaskin described the curves obtained when the optical rotatory power (polarization) of mixtures of copper sulphate, alkali tartrate and caustic soda are plotted against increasing alkali contents of the solutions. Interpretation of these curves suggests the existence of copper complexes stabilized by alkali tartrate, and the isolation of one of these, having some unusual properties, is described. Some analytical data were given for compounds formed when copper sulphate is dissolved with excess of either Rochelle salt or potassium tartrate. The bearing of this work upon the constitution and possible modification of Fehling's solution is discussed.

Lithium Alum

THE existence of a lithium alum, $LiAl(SO_4)_2, 12H_2O$, has been the subject of some discussion, and the preparation of the compound is evidently a matter of some difficulty. J. F. Spencer and Oddie (NATURE, 138, 169; 1936) prepared it by working at low temperature, but H. A. Horan and Skarulis (*J. Amer. Chem. Soc.*, 61, 2689; 1939) failed to obtain it at 0°. H. A. Horan and J. J. Duane (*J. Amer. Chem. Soc.*, 63, 3533; 1941), however, now report that in equilibrium with saturated solutions an invariant point with solution composition differing from that previously reported by Horan and Skarulis has been found, and more careful investigation of the region between these invariant points clearly shows the existence of a third phase. The results indicate the formation of a double salt of composition $LiAl(SO_4)_2, 12H_2O$. Apparently the use of concentrated solutions of purified aluminium sulphate was the only difference in technique. The existence of lithium alum, with a limited region of existence, thus seems to be established, but some care is evidently necessary in its preparation.

GREEN LEAVES AS A SOURCE OF PROTEINS AND OTHER NUTRIENTS

IT is natural that the restriction of imports, and the changes in our dietetic habits that this has necessitated, should quicken our interest in the efficient production of food in Great Britain. In a few quarters, notably the immediate vicinity of the Ministry of Food, it is maintained that there is not now, and is not likely to be in the later stages of the War, a food shortage. Fortunately for the country most scientific workers concerned with nutrition or agriculture do not share this complacent attitude. Their interest was clearly shown at the discussion organized on February 11 by the Nutrition Panel of the Food Group of the Society of Chemical Industry. The papers read dealt mainly with carotene and other lipoids; there was discussion on this subject and on a project that had been circulated beforehand dealing with the large-scale isolation of protein from leaves for the feeding of people and other non-ruminants.

The vitamin content of leaves was compared with that of various other plant products by V. H. Booth. When taken at the right time of year leaves constitute a valuable source of ascorbic acid and of carotene, but ascorbic oxidase is so widespread that it is unlikely that products derived from leaves would be of much value in practice as sources of ascorbic acid. Samples of lard containing enough carotene to give 640 I.U. per ounce (the amount officially added to margarine) were shown and also samples in which only partially fractionated grass fat had been added to give the same carotene content. The former were about as dark as normal margarine and the latter, though darker, were not unpleasantly so. It was clear, from this survey, that leaves are not of great significance as a source of any of the other vitamins except K.

During storage, the carotene content of ground-dried lucerne leaves falls. R. O. Davies described this phenomenon in some detail and pointed out that the loss was only significant if the leaf meal was not cooled after coming from the drying plant and before storage. The fall is not continuous but a steady state is reached after 1–2 weeks; A. C. Pollard, on the other hand, found a continuous fall in the carotene content of ground-dried carrot pulp. No wholly satisfactory explanation of this difference was given, but it was suggested that there may be more than one isomer of carotene present; that carotene may only be readily oxidized in those cells that have been thoroughly damaged by the grinding; that there may be a difference in the oxidizability of carotene in the free and protein-bound states. The other lipoids of the leaf were described by H. S. Jefferies. 4 per cent of dried lucerne leaves is soluble in benzene and half of this dissolves in acetone. Phosphatides constitute 35–37 per cent of the total lipoids—an unusually high phosphatide/fat ratio. Less than 3 per cent of the lipoid is sterol and there appears to be no ergosterol in lucerne although the lipoids from grasses have been shown to contain about 1 per cent.

In the contribution taken as read at the meeting[1] it had been urged that research should be undertaken on the separation and purification of leaf protein and on the cultivation of crops that would give a good yield of protein per acre coupled with a leaf that, in terms of its dry weight, was rich in protein. The most immediately available material for this research would be the normal pasture mixture, but special grass mixtures or crops such as lucerne or maize may well turn out to be the most suitable in practice. The fresh leaves would be macerated and a protein-rich liquor separated from the leaf residue; the protein can readily be separated from the liquor by a number of treatments such as heat coagulation. Experience gained in the course of work on the pigments, enzymes and viruses in leaves suggests that about one third of the protein can easily be liberated in this way; a rather larger proportion comes out if the original crude protein content of the leaf is high, that is, more than 18 per cent. The leaf residue would therefore still contain about two thirds of the protein as well as all the fibre. From 140,000 acres it should be possible to prepare sufficient leaf protein to supply 1 gm. per head of population every day for a year. The aim of the research would therefore be to 'skim' off part of the protein of the leaf in a form suitable for the non-ruminant while leaving a residue suitable for use as a feeding-stuff for ruminants. If the research were successful, several advantages are claimed for this method of husbandry. The yield of protein of high biological value would be higher than that attainable from an acre by any other means; the fibre residue would be of relatively constant composition and of considerably greater feeding value than the hay that would probably have been made on the land had it not been used for this purpose; there is good reason to think that leaf protein would cost less than the other proteins that can be produced in Great Britain.

A. C. Chibnall agreed with the general principle of leaf protein extraction, but thought that it would be premature to start any research on these lines until our agricultural policy had undergone thorough reorganization. Difficulties were predicted both in the operation of an acreage sufficient to make a significant contribution to our protein supply and in the maintenance of a high leaf protein content. These difficulties did not impress R. O. Davies who has experience of farming more than ten thousand acres of lucerne; for five months out of the year the crop contained 17–28 per cent of crude protein.

Figures for the amino acid composition of protein isolated from cocksfoot grass were given by A. C. Chibnall, and he pointed out that this fraction of the total leaf protein contains all the amino acids that are known to be essential in the nutrition of the rat, in about the right amounts. Estimations of some of the amino acids in proteins from the leaves of several plants suggest that these proteins form a group of fairly uniform composition and of high 'biological value'. The need for feeding experiments to supplement these analyses was stressed by S. K. Kon, for leaf protein fed in the form of dried grass had a lower 'biological value' than Chibnall's figures would lead one to expect. These experiments, as A. L. Bacharach pointed out, should not be confined to the rat, but should be extended to some of the animals in the nutrition of which we are more immediately interested.

N. W. PIRIE.

PINE SHOOT BEETLES

An interesting account of pine shoot beetles has recently been published by Dr. Leon Ossowski (*Scot. Forest. J.*, 55. Part 2; 1941; Douglas and Foulis, Edinburgh). The author states that any forestry publication, British, Polish, German or Russian, is likely to contain an article on bark beetles and more especially the pine shoot beetles, which proves the destructive nature of these pests. In spite of many natural enemies the two pine shoot beetles are very plentiful, largely due, as Dr. Ossowski correctly states, to the usual technique of planting, "for planting concentrated in one year or on a single species gives a breeding ground for the beetles. Where we have natural regeneration and plantations of different ages and different species the beetles are rarely met with."

Equally correctly the author advocates that, in future, planting should not be confined to Scots pine, European larch and Norway spruce (33⅓ per cent of each) but that 30 per cent or even half of a plantation should consist of deciduous trees. It is an undoubted fact that in those temperate countries where considerable tracts of conifers either pure or mixed have been planted, sooner or later the areas have been visited by serious epidemics of pests—frequently the various bark beetles. There are others, for example, the plague of the pine noctuid (*Panolis piniperda* Panz) in Brandenburg and Pomerania in Germany, which laid waste thousands of hectares of coniferous woods during 1921–25; or the great devastation in the spruce forests in the Vosges (1903–05) by bark beetles. In spite of the well-known examples of widespread attack and heavy losses the lesson is difficult to learn apparently—for the pure conifer plantation is still being planted on a wide scale in temperate climates.

The author discusses some of the well-known methods of combating attacks and incidentally affords an interesting side-light on his own country, Poland.

"A striking example of the motto 'Back to Nature' is given by the woodlands of my own country. While in West Poland the woods are mainly coniferous, those of the North and North-east Poland are of a more mixed type with natural regeneration. Between 1920 and 1939 there were in West Poland two attacks of pine noctuid (1922–1925 and 1931–1933), two of the pine moth (*Dendrolimus pini*) and the pine looper (*Bupalus piniaria*) and one of the nun moth (*Liparis monacha*). The damage done by the insects was enormous and, so far as I can remember, through the noctuid plague of 1922–25 about 250,000 hectares of coniferous plantations must have been ruined, and in 1931–33 it cost 3,500,000 zloty (£140,000) to combat the evil. In the forests of North and North-east Poland, on the other hand, there were no great disasters from insect pests to record, and if here and there destructive insects appeared the trouble was only local and the loss not very great. As already stated, mixed plantations and a combination of tree groups of different ages give the best defence against bark beetles and destructive insects in general."

Research and experience are showing that much the same general rule applies to the broad-leaved species of fine timbers in the tropical and sub-tropical forests. It is becoming equally plain that the ordinary practising forester (or agriculturist, for that matter) finds it difficult to appreciate the fact until he faces a disaster.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Saturday, February 28

ROYAL SANITARY INSTITUTE (at the Nuffield Institute of Clinical Research, Oxford), at 10 a.m.—Mr. H. H. Crawley: "The Storage of Emergency Drinking Supplies"; Mr. Stewart Smith: "Administration of the Government Evacuation Scheme".

NUTRITION SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10.30 a.m.—Conference on "Food Production and Distribution in relation to Nutritional Needs". (Speakers: Sir John Orr, F.R.S., Dr. N. C. Wright, Mr. E. T. Halnan, and Sir John Russell, F.R.S.)

Monday, March 2

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Capt. G. S. Andrews: "Projects for the Alaska Highway Route".

Tuesday, March 3

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "Metals", 1: "Metal Architecture".*

Wednesday, March 4

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. Llewellyn S. Lloyd: "Modern Science and Musical Theory".

Thursday, March 5

TOWN AND COUNTRY PLANNING ASSOCIATION (in the Dome Lounge, Dickins and Jones, 224 Regent Street, London, W.1), at 1.20 p.m.—Rt. Hon. Sir Montague Barlow, Bart.: "Decentralization and the Location of Industry".

Friday, March 6

PHYSICAL SOCIETY (OPTICAL GROUP) (at the Science Museum, Exhibition Road, London, S.W.7), at 11.15 a.m.—First General (Business) Meeting; at 11.30 a.m.—Dr. W. M. Hampton: "Problems relating to Optical Glass"; at 3 p.m. (in the Small Physics Lecture Theatre of the Imperial College, Imperial Institute Road, London, S.W.7)—Mr. R. J. Bracey: "A Multi-Purpose Collimator"; Mr. J. W. Perry: "Thermal Effects on the Performance of Lens Systems".

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting; at 4.45 p.m.—Prof. J. W. Munro: "Entomology of Commerce".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, London, S.W.1), at 5.30 p.m.—Mr. B. J. Tams: "The Operation of the Mechanical Engineering Section of the Central Register in War Time".

Saturday, March 7

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. W. P. D. Stebbing: "A Review of References to Geology and Allied Subjects from the 16th Century" (Presidential Address).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

GRADUATE LECTURER IN ENGINEERING—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (March 7).

LECTURER IN CIVIL AND MECHANICAL ENGINEERING—The Secretary, *Northampton Polytechnic, St. John Street, London*, E.C.1 (March 16).

SCIENTIFIC ASSISTANT (woman not liable for National Service)—The Deputy Director, Imperial Bureau of Pastures and Forage Crops, Agricultural Research Building, Penglais, Aberystwyth (March 21).

PROFESSOR OF EDUCATION—The Registrar, University College of Swansea, Singleton Park, Swansea (April 11).

ASSISTANT MECHANICAL ENGINEER for the Electrical Branch of the Nigerian Government Public Works Department—The Secretary, Central Register, Ministry of Labour and National Service, Queen Anne's Chambers, London, S.W.1 (quoting reference O.N.C.793).

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

RELATION OF SCIENCE TO POLITICS

THE value of the Conference on Science and World Order in London last September lies largely in its emphasis on the increasingly close relation between science and government. For all its demonstration of the contribution which science could offer to the solution of the many problems of human welfare involved in the realization of the four freedoms, the Conference is more significant for the evidence it affords that the fundamental problem is that of securing the right relations between science and government. The full resources of science must be brought to bear on the problems of human welfare without impairing the freedom of thought, investigation and teaching upon which the very existence of science depends. While the independence of science is thus safeguarded, means must be found for securing the effective application of the knowledge acquired by disinterested and impartial research to the solution of social and economic problems and the service of human needs. The problem of the relation of knowledge and action is once again demanding an answer in terms of the needs of to-day and not the traditions of yesterday.

The discussions which have taken place since the Conference, and centring to some extent around the presidential address of Sir Henry Dale at the recent anniversary meeting of the Royal Society, on the relation of science to politics, like the conferences on science and the war effort convened by the Association of Scientific Workers, attest that the Declaration of Scientific Principles has been taken to heart by scientific workers. Conscious of the dangers to science and society inherent in the relations between science and politics, they are seeking to determine the conditions of advance. That much at least lies behind the various proposals regarding the organization of research in the social sciences and the establishment of a central institution for that purpose.

The address on Science and International Politics which was delivered by Sir Richard Gregory at the Royal Institute of International Affairs on February 2 (see p. 261 of this issue) should go far to clarify thought on this subject, which certainly must not be shunned because it bristles with difficulties and dangers. Admittedly there are departments of civil life which could with advantage make fuller and more systematic use of the scientific methods of inquiry into the factors which determine human conditions and potentialities to-day. To turn our back deliberately on such possibilities and to make no attempt to use that scientific knowledge which is our greatest power for social and political action is to deprive the Atlantic Charter of meaning, if not indeed to endanger the winning of the War itself.

Once we admit, as Sir Richard points out, that there are political leaders who can scarcely be said to take account of the changing conditions of life due to the applications of new scientific knowledge, either in the present or for the future, scientific workers can not rest content as citizens. They must make some effort to influence those in charge of the forces of science and who carry the responsibility of seeing that these are used effectively for the progressive welfare of the community. They must at least attempt to secure that the strength and disposition of the forces of science are given full consideration in all social and political campaigns. The fact that, as Sir Richard points out, few men of science feel able to transfer their trained habits of thought, does not absolve the body of scientific workers, either corporately or individually, from the responsibility of attempting to transfer to the consideration of social and political problems their training to face facts before arriving at judgments.

This, of course, is exactly what General Smuts urged in his Sidgwick Lecture on Democracy. It is only by applying to political problems the principles of independent inquiry and impartial judgment demanded of investigators in all branches of natural knowledge that politics can become a science and scientific workers as such can contribute to its advancement. Without this spirit and purpose, science and politics are best placed in different categories.

What has marked numerous discussions on social and economic questions of recent years is, however, the extent to which by making action possible on the basis of ascertained facts, science has taken problems out of the purview of party politics. Nutrition is an outstanding example of this kind. Political action is still required, but the question is no longer a party issue, and the power to be applied is that required to overcome vested or private interests as opposed to those of the community.

The natural extension of the boundaries of knowledge by the application of scientific method may thus, it is true, gradually extend the field within which action free from political prejudice is possible. We can not, however, rely on that process alone if effective action is to be taken to deal with many of our more urgent social problems before they bring worse in their train, any more than we should imagine that the scientific method alone will provide a solution. The effective implementation of this process involves three desiderata, with each of which the scientific worker is concerned: leaders and administrators competent to assess the results of scientific work and ready to apply them to the solution of the problems of to-day; a body of active younger scientific workers not merely extending the boundaries of knowledge but also able to formulate the questions to be asked, the problems to be attacked; and a body of public opinion sufficiently informed and powerful to overcome the opposition of any sectional interest to policies or action initiated in the general interest.

Prof. A. V. Hill's address last year to the annual general meeting of the Parliamentary and Scientific Committee contained specific proposals for forwarding the second of these needs, and the Scientific Advisory Committee, of which Lord Hankey is chairman, may yet do much to implement the first. It is the third condition, with the implied task of educating public opinion, that is possibly the most fundamental of all and which has yet to receive the attention it deserves from public opinion. Sir Richard Gregory's address is a contribution in this field which once again should earn him the gratitude of scientific workers.

There is, however, a further point to which Sir Richard directs attention. Repeatedly observers have noted the difference between the success of the League of Nations in its non-political work such as that of the International Health Organisation or the Opium Commission where technical considerations were the dominant factor, and its failure in those dominated by politics. Sir Richard suggests that international politics in which the world is a unit, of which all men are citizens with rights and duties to be adjusted wisely with the object of ensuring progressive development everywhere, is the field into which the international spirit of science can enter without being regarded as an intruder or becoming involved in controversial national politics. National boundaries have little relation to the distribution of national resources and less to the needs of modern life. All communities can share in the achievements of scientific discovery and invention, and the tendency towards larger political units gives promise of further expansion into a commonwealth of the chief free peoples of the world.

Such a commonwealth can only be secured by consent, and as Sir Richard reminds us, no new world order can be stable unless each nation is free to follow its own lines of cultural development, and does not seek to deprive others of the same liberty. With such a co-operative alliance in mind—already embryonic in the fourth point of the Atlantic Charter—the services of science can be used to shape the course of international politics. As already noted, advancing knowledge is taking welfare policy out of the field of party politics both in the national and in the international spheres. Knowledge of natural objects and phenomena is the foundation upon which modern civilization is based. It is continually revealing new sources of supply of materials and power to expand this structure. Applied science has provided the means of making the world's abundance available to all men, and the aim of international politics should be to see that the supply is adjusted according to the need for its use.

Such an outlook on world order is as implicit in the Atlantic Charter as in the four freedoms of President Roosevelt, and it should already be clear that its realization depends very really on the co-operation of men of science. While, however, what exists in the world, and what uses can be made of it, are discovered by scientific inquiry, what action is taken on this basis depends upon communities and their governments. For this reason the view that the sole function of men of science is to study and discover natural facts and principles without regard to their social implications is no longer tenable. Not only have they special responsibility for recording their opinion in matters in which their pursuits affect the welfare of the community, but also the obligation as citizens to assist in the establishment of a rational and harmonious social order out of the welter of human conflict into which the world has been thrown because the powers they have released have not been rightly used in the service of mankind as a whole.

It is at this point that Sir Richard's address is linked up with an article "Science to Re-build" in the November issue of *Current Science* (India). Admittedly the Atlantic Charter gives new hope for the establishment of a world order in which the fundamental rights of men and communities will be defined and acknowledged and in which science will be able to serve more effectively the needs of mankind. Such rights and principles must, however, be formulated more clearly than has yet been done if reconstruction is to prove effective, and science can well combine with politics, as Sir Richard suggests, in the determination of such principles and in arriving at a sound basis for the constitution and judgments of a court of international politics.

The article in *Current Science* indicates further steps to be taken, notably in the extension of scientific knowledge in those fields where it would assist man to acquire control over his own nature corresponding with his control over material resources. Besides, it is essential that even such declarations as the Atlantic Charter should be submitted to careful and scientific scrutiny. Already there have been some differences of interpretation of, or at least of emphasis on, the various clauses and if misunderstandings are to be avoided certain of these points must be elucidated in the near future.

In the modern world to-day not even an Anglo-American declaration of policy can avoid facing the colour question, and the article in *Current Science* is on firm ground in directing attention to the omission of any reference to such countries as India, and again in insisting that the first axiom in world planning is that the prime motive force of life is hunger, which knows no distinction of colour. No world order which does not take into account the needs of coloured as well as of the white races can be regarded as either scientific or durable.

On other specific points of the Atlantic Charter this article is equally searching. In regard to territorial settlements it points out that an expert body of economists, demographers and other specialists will be required to furnish the necessary advice on particular settlements if such settlements are to be free from any sense of unfairness. It challenges the durability of any settlement respecting the right of all peoples to choose the form of government under which they will live, unless in practice that government is some form of democracy. It raises the question of the responsibility of scientific men in respect of disarmament with reference to work likely to be useful for military purposes, and suggests that such researches should be submitted for examination and their report on results for control by an international agency.

In the field of economic development some of the implications of the Charter are indicated, such as open markets, the supply of technical knowledge and skill and industrial machinery, and an international bank or finance corporation to lend money for development purposes, free from political, military or trading obligations.

It is abundantly clear that there is an immense field in which fundamental thinking is required before we can implement many of the principles of the Atlantic Charter or assess rightly the schemes of reconstruction which must be worked out in readiness even in the dark and exacting days of war. To that thinking science has much to contribute. Corporately and individually scientific workers can also do much to forward the task of reconstruction in fields where they bear special responsibility, as has already been recognized by engineers, physicists, medical men and architects in the formation of special planning committees or commissions. There are, however, many sections of scientific workers who have shown little sign of recognition of their responsibility in this field and it may well be hoped that Sir Richard Gregory's address will not only stimulate such to action, but also scientific workers generally, to consider more carefully the appropriateness and effectiveness of the machinery which already exists for integrating the relations of science and politics, whether at the top in the Scientific Advisory Committee, in the arrangements for widening the outlook and experience of the active young minds engaged in scientific work, to which Prof. A. V. Hill has specially referred, or in that fundamental task of educating the public mind so that it can reach sound decisions and supply the power to overcome private interests which hold up action demanded by the public interest. As these lines are explored with the world vision and perspective which Sir Richard emphasizes, the relations between science and politics will become more clearly delineated, while the claims of science to be free from any form of pressure in pursuing her work are established beyond challenge.

SKILLED MAN-POWER IN THE SERVICES

THE importance of wise utilization of skilled man-power if we are to develop the maximum production and war effort has been emphasized by recent events, and its realization has been implicit throughout recent debates and discussions in Parliament and elsewhere. If the second report of the Beveridge Committee on Skilled Men in the Services* will not altogether dispel misgivings on that ground, there are certain points on which it gives welcome reassurance.

The Committee is able to answer unhesitatingly that the Navy is using the skilled man-power at its disposal with due economy and effect, except in regard to naval reservists, where the measures already taken for transfer of qualified men to skilled work need to be repeated and reinforced until they achieve success. Better use is being made of skilled engineers in the Navy than in either the Army or Air Force. Although the problems in the Navy are simpler, they would not be solved as completely as they are, unless the Navy possessed, as it does, good arrangements in respect of trade testing, search for talent, technical training, review of establishments, interim use of engineers and self-scrutiny. The trade testing of the Navy is centralized, standardized, and objective. Any skilled engineer volunteering for the Navy knows that he will have a fair test, and that if he passes, he will be ranked forthwith as a petty officer and employed as an engineer. There is organized search for talent in the Navy and, while in the development of new training establishments the Navy has less to show than either of the other Services, the regular establishments are excellent and their procedure has been adjusted to war conditions. By better use of some of the naval reservists, the Committee estimates that it should be possible to meet some 10 per cent of the demands of the Navy for skilled men during the period ending March 31, 1942, but substantial additional numbers will be required.

---

* Committee on Skilled Men in the Services: Second Report and a Memorandum by the War Office. Pp. 74. (London: H. M. Stationery Office, 1942.) 1*s*. 3*d*. net.

The Air Force stands intermediate between the older Services, in size, in rate of expansion, and in the complexity of its problems. It is also not so clear of complaints of unused skill as is the Navy; but, while it has nothing comparable in scale to the misfits and misapplications that appear in some parts of the Army, it shows sufficient misfits to call for expansion of the measures which have already been taken to deal with such cases. The Committee considers that the machinery for sorting, selecting and trade testing should be re-examined, and such barriers as remain should be reconsidered.

The situation with regard to the Army is less satisfactory, and substantial changes of organization and machinery are likely to be required before it can be said that the skilled man-power already at the disposal of this Service is being used with due economy and effect. There are, of course, several factors which have made the adjustment of supply to demand and full use of skilled men harder for the Army than it is for either of the other Services, or for civilian industry. The Army has expanded more than either of the other Services and much more than the munitions industries, and its rate of growth has been subject to violent fluctuations. An industrial organization which after a comparable period of growth was subjected to a similarly thorough scrutiny would be lucky it it failed to show many misfits.

At the beginning of the War, the Army received numbers of men, either called up as territorials and reservists or posted as militia, in regard to whom it was not possible to exercise selection in assigning them to appropriate trades or units. In addition, the Army, while growing, has had to change its character by progressive increase in the proportions of armoured and mechanized divisions. The character of the War, with the serious loss of equipment in France and the subsequent prolonged restoration and waiting in England, have added to the difficulties of adequate use of the man-power in the Army, but one of the most fundamental difficulties is the structure of the Army as a combination of distinct corps and of units, often with strong local associations or sectional traditions, and consequent obstacles to transfer.

All the investigations of the Committee point to the conclusion that the reservoir of unused engineering skill already in the Army is greater than the revised requirements for skilled men of engineering and allied occupations laid before it by the War Office. While this does not mean that all such requirements can be met from within the Army, it does involve certain major changes, notably the technical review of establishments, the pooling of mechanical reserves, and the reorganization of selecting, sorting and trade-testing arrangements. The older Army training establishments are regarded as excellent. Its new training establishments are an improvisation deserving of great praise; good in themselves, they need to be fitted more closely into the organization of the Army as a whole, with better selection of trainees and with closer adjustment to the practical problems which the trainees will have to solve.

The report advances two major proposals for consideration, rather than as recommendations: enlistment into the Army not for corps, but as a single Service; and the establishment of a Corps of Mechanical Engineers. Fundamental to this and to the vital changes recommended, and a condition of their achievement, is that mechanical and electrical engineering, as distinct from civil engineering, should be given their proper place and authority in the higher councils of the Army. Review of establishments on the lines suggested may achieve substantial economies of skilled men in the Army without undue risk, but the vital need is for a new outlook, for new methods for new tasks. Mechanization of an army, as the Committee observes, should begin from the top.

When full allowance has been made for all disturbing factors, and in spite of the vigorous efforts made in all three Services to bring about a re-mustering and using of men according to their skill, the extent to which men of rare skill find that skill unused in the Forces, in the Committee's judgment, remains disturbing and surprising. It is fully recognized that many forms of skill which are valuable in peace cannot be turned to account in war, and that the essential problem of skilled men in the Services is that of how to be ready for emergencies without wasting more than the irreducible minimum of skill in standing-by. The organization of war is largely a question of priorities, and in regard to engineers the Committee has been guided by two principles: the first priority in war is for whatever may be needed to keep the machines of war in action; and second, in war engineers are for those who can and will use them as engineers.

The Committee points out that, on the first principle, skilled engineers and spare parts are alternative means of securing the maintenance of machines of war, and its lucid argument shows a clearer grasp than the War Office in its accompanying memorandum of what General Wavell termed the "mechanism of war" and the real foundation of military knowledge in his lectures on "Generals and Generalship". While, therefore, the full investigations leave unchanged the main conclusion of the interim report that an increase in the skilled personnel of the

Services is inevitable, and that more engineers must be drawn from civilian industry for the Services, there is a clear possibility that the unused reservoir of engineering skill in the Army is large enough and varied enough to meet all the requirements submitted to the Committee for men of engineering skill.

The whole tone of the War Office memorandum published with the report betrays a disquieting failure to see the situation in its true perspective of either time or resources, and the subsequent speech by the Secretary of State for War in the House of Commons was even less reassuring. Some of the points raised in the War Office memorandum deserve careful consideration, but a frame of mind and a condition of organization which have already taken three and a half months to produce this memorandum on the report with the remark that so important a recommendation as the creation of a Corps of Mechanical Engineers is still under consideration are profoundly disturbing. The War Office cannot avoid the issue by the naive suggestion that the Beveridge Committee brings to its task merely the standards of industrial practice. The problem of a trained, equipped and maintained army and its industrial background must be seen as a whole, and if the Army's present leaders cannot see the problem thus and weed out wasters as well as waste at every rank, they must be replaced by those who can.

It should not be thought, however, that in spite of the procrastination of the higher command in dealing with the two major proposals, the Army is making no attempt at a more scientific use of its resources of man-power, skilled or unskilled. Lieut.-General Sir Ronald Adam recently gave an encouraging account of the selection tests for avoiding misfits which have already been developed under the Advisory Committee, composed of Prof. J. Drever, Dr. C. S. Myers, Prof. F. C. Bartlett and Prof. C. Burt, appointed last June to assist the Director of Personnel Selection. Moreover, a thorough analysis is being made of every job in the Army and experiments are being made in leadership tests, based to some extent on German practice, for use in selecting men for training as officers, and directed to ensuring that a leader is more intelligent, has quicker reactions and more personality than the men he leads.

General Adams's statement that a large-scale experiment has been started by enlisting men into a general service corps and putting them through a basic training course before deciding for which corps they are best suited indicates a greater receptivity to new ideas than is apparent in the War Office memorandum.

A more promising attitude is also to be found in the War Office observations on the twenty-second Report of the Select Committee on National Expenditure, which have now appeared in the Select Committee's first report of the 1941–42 Series. The memorandum states that the directorate of Selection of Personnel has a staff of 15 officers and 150 N.C.O.s (including A.T.S.) and has been approved to carry out selection tests on the personnel both of intakes and of existing units. While upholding the value of the military interview, the memorandum recognizes that the selection test is complementary and that the value of the interview will be greatly increased if the interviewing officer has before him the result of the man's selection test. The War Office would welcome a system of compulsory intelligence testing of all intakes, regardless of their preference, to be carried out under the auspices of the Ministry of Labour.

Discussing the Select Committee's recommendation for the establishment of central depots for classification before posting, the same argument is advanced as that against the proposal of the Beveridge Committee, but it is admitted that the basic training centre system is already in use for the A.T.S. As regards the discharge of unsuitable personnel, the War Office urges that this must be weighed carefully against the man-power situation. The War Office agrees that intelligence is one of the principal factors in the make-up of a potential officer, and that no candidate should be sent to an officer cadet training unit whose intelligence as measured by a test does not reach a certain standard. The time to apply such a test is under investigation, and it is proposed that all candidates should be given an intelligence test before their interview by a Command Interviewing Board.

These observations will do something to reassure opinion as to the readiness of the Army to rectify past mistakes and improve its technique and organization in these vital matters. Sir Edward Grigg's speech following Capt. Margesson's in the debate on the Army Estimates, was, however, somewhat disturbing from the point of view of the outlook betrayed. The statement that only 9 per cent of officers in the Army had had a university education can reflect equally on the capacity of the universities to train men for leadership and on the ability of the Army to recognize potential leaders. But it cannot be discussed without some knowledge of the numbers of university men available for meeting Army requirements and of the extent and nature of the Army's requirements for officers.

The statement should not be allowed to pass unnoticed, because of the implication contained in the whole context that a high standard of education is unnecessary in meeting Army requirements. Fundamentally, it may well be found that the blows which we have recently suffered are due at least in part to defects of leadership from top to bottom of the Services, which can in turn be traced to the neglect and indifference of people and Government alike to the real issues of education. Sir Edward Grigg fundamentally misconstrued the attack on recruitment of officers from the public schools. The objection to that system is that it places recruitment on a class basis, and does not tap the larger reserves of leadership available in the nation. Moreover, until some system of intelligence test is imposed in accordance with the War Office memorandum, on all entrants to officers training establishments, from Sandhurst and Woolwich downwards, there will be no satisfactory obstacle to such factors as social or economic position admitting men ultimately to positions of responsibility which they lack the character or ability to discharge.

The appearance of the Beveridge Report and the accompanying memorandum, however, should not be without a steadying influence on the public mind. They represent a great challenge to constructive thought which scientific workers should be quick to accept. Their implications strike far into the causes of our present difficulties, and there are few indeed who cannot see in this analysis some bearing on their own task and part in the war effort, and an indication of how that contribution can be increased. The solid reasons for confidence contained in the Report, and the picture of admirable work already being done, only emphasize the urgency for doing quickly what more remains to be done. On every citizen lies the responsibility for seeing that there is no waste of skill, men or material, and when he has done his or her utmost in his own special sphere, there lies that corporate responsibility of compelling effective and urgent action, through Parliament and the sheer force of public opinion, wherever indifference, neglect, incompetence or lack of interest perpetuates inefficiency and waste.

FIREFLIES

Living Light

By E. Newton Harvey. Pp. xv+328. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1940.) 24*s.* net.

A GLOW-WORM in the grass and fire dripping from the oar are two things which once seen are never to be forgotten. Faraday, posting through Italy with Sir Humphry Davy, found "entertainment and delight" in the fireflies by the way. When the *Challenger* entered the Guinea Current, soon after her voyage began, the sea was "a perfect blaze of phosphorescence"; and long afterwards Wyville Thomson used to tell us how the Pyrosomas glowed in the water like bars of white-hot steel. Sir Joseph Banks had found his *Medusa pellucens* (akin to our *Pelagia noctiluca*) in the same waters, and thought it the most splendid of the luminous inhabitants of the ocean; its flashes of light, he said, were so vivid as to affect the sight of the observer. And Humboldt speaks with his great voice of that "magic brightness", which is part of the joy of those who, like himself, have a peculiar predilection for the sea.

The shellfish (Pholas) which, according to Pliny, seem on fire as they go down your throat—*velut igne lucentes in tenebris, etiam in ore mandentium*; the splendid brief intensity of the Bermuda fireworm; the little lanterns of the deep-sea fish which the dredge brings up and which Dr. Beebe goes down to see; the little squid at Messina which surround themselves with liquid fire instead of a screen of ink—all these are part of the multitudinous phenomenon which Prof. Newton Harvey lovingly and enthusiastically describes. Every now and then our wonderment grows greater still over some new feature of the display, such as the flashing of certain fireflies in periodic synchronism. "At one time [in Siam] every leaf and branch appears decorated with diamond-like fire; but soon there is darkness, to be again succeeded by flashes from innumerable lamps."

For thirty years at least Prof. Newton Harvey and the students in his Princeton laboratory have been studying the phenomena of luminescence. They have turned out among them a host of well-known papers, and his friend, Prof. Ulric Dahlgren, has been as busy on the histological side as Prof. Harvey on the experimental and biochemical; indeed, Prof. Harvey seems just a little weighed down in the writing of this book by the superabundance of his own knowledge. He gives us a useful bibliography of some thirty pages; but this, he tells us, is a mere nothing, so vast is the literature of the subject. A hundred years ago, in his famous work, "Das Leuchten des Meeres", Ehrenberg cited between four and five hundred older books and papers, very few of which Prof. Harvey finds room, or thinks it necessary, to quote again.

But to sum up. After giving a third of his book to the description of all manner of phosphorescent organisms, Prof. Harvey goes on to deal with the physics, the chemistry and the physiology of the subject. He describes the various types of luminescence from the physicist's point of view. He goes on to the chemistry of luminescence, and is particularly interested in the curious substance described sixty years ago by Dubois as luciferine, along with its enzyme luciferase. An interesting chapter follows on the physiology of luminescence; and the last chapter of all (which interests me less) is on the physical nature of light. Of the many illustrations, some are curiously beautiful, especially the frontispiece, which shows some of Dr. Beebe's deep-sea fishes in pursuit of little scarlet and luminous squid.

The author is generous in crediting to its discoverer almost every fact which he records; but it cramps his literary style somewhat to quote fifteen or eighteen authors on a page, along with the dates of their several publications. The book has its share of misprints, but its blunders, so far as I can see, are few. The Nemertean worms are not so called from the 'unerring' aim of their proboscides, but merely as a literary allusion to Hesiod's description of the father of all the Nereids, the wise Old Man of the Sea. And as to Fulgora, whose time-honoured reputation as a 'lantern-fly' now comes in question, it would be all very well to call it a 'bug', but to call it a *beetle* won't do.

D'Arcy W. Thompson.

THE LIVING SPIDER

The Comity of Spiders

By Dr. William Syer Bristowe. Vol. 2. (Ray Society Volume for the Year 1940.) Pp. xiv+229–560+3 plates. (London: Bernard Quaritch, Ltd., 1941.) 25*s.* net.

ALTHOUGH Dr. Bristowe writes in his preface that the War has affected his work on spiders and even his enthusiasm it is difficult for the reader to detect many signs of this in the volume which concludes the work first published in 1939. The subjects with which he is now concerned are food and its capture, danger and its avoidance, courtship and mating. On these matters he gives us a summary of his own investigations—which began, he tells us, at the age of four—supplemented by some contributions from the work of other araneologists.

In the first chapter, which deals with the capture of the prey, Dr. Bristowe analyses the varied methods employed, classifies the types of web and gives his views on the difficult subject of the evolution of the web. The clue that he offers in solving this problem is the suggestion that silk was first used as a protective cover for the eggs; at the same time the tracing of the evolutionary path is complicated by the fact that the same type of web may more than once have arisen independently.

In discussing the nature of spiders' food, Dr. Bristowe corrects the vague impression that spiders generally will eat any small living animal. He does this by a very full account of experiments on the acceptance or refusal of many insects and other arthropods by many kinds of spider. The insects are passed in review, order by order, and precise information is given of the results of offering them to spiders of many genera. Usually the actual species of spider and of insect are recorded, and the result is a large body of exact and reliable information on a subject which has not previously attracted the attention it is now shown to deserve. One of the most interesting of the many points emphasized is the fact that often, after biting and rejecting a nauseous insect, the spider is seen to "wipe its mouth" on a convenient leaf or the neighbouring wall.

Dr. Bristowe next turns his attention to the opposite side of the picture: from those animals a spider will eat to the correlative question of the animals that will eat a spider. The same admirably precise information is recorded. The enemies, parasites and predators are taken order by order. The longest sections here are concerned with Ichneumons and other spiders among invertebrates, with fish and birds among vertebrates. The great popularity of ornithology enables quantitative estimates to be given here, and the section concludes with a striking table of the estimated spider-consumption of sixteen species of British birds. These range from starlings, credited with a total consumption of 10,000 million spiders annually, to rooks, which are responsible for a mere twenty-five million. The spider's protection against its enemies seems to be chiefly the well-tried methods of protective resemblance and mimicry.

In the chapter on mating habits Dr. Bristowe is writing on a subject that he has made peculiarly his own. He now gives us a survey of the whole process, from the remarkable sperm-induction to the male spider's chance of escaping from his mate with his life.

Dr. Bristowe dedicates this second volume to the naturalists of all nations, and this fact, together with the curious title of the book, may be taken as an expression of his intention to write as a naturalist rather than as a biologist or a zoologist. In so doing he has shown that it is possible to learn a great deal about the habits of animals and to understand, so far as that may be done, something of their mode of life, without the use of any theory of animal behaviour. He is concerned only to describe events, and he does so in a manner that, while he now avoids anthropomorphic and specifically teleological statements, gives a picturesque and even an exciting impression of what he has seen. But he refrains from debate as to whether reflex, tropistic or instinctive behaviour gives the best method of scientific description of any activity.

In his last chapter, however, he deals with a question of broader biological significance, namely, the dominance of Linyphiid spiders in temperate regions. He concludes that this is due to the favourable climate, the abundant food supply and a partial immunity from the attacks of some of the spider's enemies.

The book is illustrated chiefly by clear line diagrams with a few photographic plates, which, it must be confessed, demonstrate the marked superiority of line over photography where spiders are concerned. A word of praise should be given to the apt choice of unusual quotations which have provided the chapter mottoes. Nor should the industry which has compiled the very useful index of every specific name used in British spider literature be unmentioned.

Taken together, Dr. Bristowe's two volumes constitute a notable piece of work and one which should facilitate and encourage the study of British spiders when international affairs once more permit the prosecution of peace-time occupations.

T. H. SAVORY.

FOURIER SERIES AND SOME APPLICATIONS

Fourier Series and Boundary Value Problems

By Prof. Ruel V. Churchill. Pp. ix+206. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 17*s*. 6*d*.

IN the development of human knowledge, and particularly in science and mathematics, any great discovery stands out as a beacon to mark progress made in a certain direction. But it reveals also paths of possible further advance upon which other research workers may begin to tread. In time, these workers may light up new beacons until a whole region becomes illuminated with increasing intensity. The discrete points of light thus tend to lose their separate identities by merging themselves into a flaming torch—discontinuity seems, in fact, to become continuity. So, in particular, one great mathematical discovery opens the way for many others until previously accepted concepts become broadened into a much more powerful generalization which, as history reveals, so absorbs the contributory steps that they almost lose their individual entities. This fact is well illustrated by the subject of the volume under review.

While trigonometric series were first introduced in analysis by Daniel Bernoulli and Euler in connexion with problems on vibration, and by Legendre and Laplace in the theory of gravitational potential, it was the great work of J. B. J. Fourier (1768–1830), in showing that quite arbitrary discontinuous curves could be represented analytically by means of infinite trigonometric series, that opened the way to laying the subject upon a sure foundation. In the process, as Boyer remarks[1], "the attitude towards the function concept became broader". This was made manifest by the subsequent work of Cauchy in which a new notion of continuity was developed. One modern writer has declared[2] that the theory of Fourier series is "one of the most beautiful results of analysis and serves as an indispensable instrument in the treatment of nearly every physical problem".

Prof. Churchill's volume admirably illustrates this truth although the author only claims his book to be an introduction to the subject. It is concerned with the two related and general problems: the expansion of an arbitrary function into a Fourier series, and the boundary value problems in the partial differential equations of physics and engineering. Before dealing with the essential theory of the Fourier series, the first three chapters are devoted to an introduction to the subject, the partial differential equations of physics and a succinct account of orthogonal sets of functions. Chapters 4 and 5 treat of the Fourier series proper, their various forms, fundamental properties and Fourier integrals, all of which are well discussed. Applications to boundary value problems then follow as the main subject-matter of the remaining four chapters. In these, the essential theoretical aspect, such as uniform convergence, uniqueness theorems, etc., are considered in their relation to the solution of the important problems connected with vibration, temperature, electric potential, and so on. Finally, Bessel functions and Legendre polynomials, with their respective applications to radiation, vibration and gravitational potential due to a circular plate, bring a very interesting and instructive course to a conclusion.

The book is excellently printed and abounds in illustrative examples and problems in wide variety for the student. Answers to most of the latter are provided, and references for further reading are given at the ends of most of the chapters.

The author's aim to render the course "both elementary and mathematically sound" has been skilfully carried out and the book is a valuable contribution to the subject.

POLYMERIC REACTIONS

High Polymeric Reactions

Their Theory and Practice. By Prof. H. Mark and R. Raff. Translated from the Manuscript by Luise Harris Weissberger and I. P. Irany. (High Polymers, Vol. 3.) Pp. xiii+476. (New York: Interscience Publishers, Inc.; London: Imperia Book Co., Ltd., 1941.) 39s. net.

THIS is the first book exclusively devoted to an examination of the mechanism of polymerization reactions. Such reactions can now be well enough controlled to make practicable quantitative measurements on the rate processes involved. Consequently it becomes possible to inquire how chemical kinetics can throw light on the nature of the elementary types of reaction in the polymerization mechanism. In this respect it is a virgin field, and in spite of considerable effort there is still much to be done before a clear and reliable picture of polymerization may be constructed.

Admittedly the problem is much simplified by the development of the detailed theory of chain reactions started some fifteen years ago, but the theory of polymerization reactions has to do a good deal more than the straightforward chain theory. Here in essence it was necessary to deal with only two active molecules or chain propagators, and establish their identity and reaction velocity coefficients. With polymer reactions, on the other hand, the nature and reactivity of *each* polymer must be determined not only as a matter of kinetic interest but also as a prerequisite in calculating concentrations of the several polymers formed after the reaction has ceased. In addition, there are further complications. Linear chain polymers are not necessarily built up by a chain type of mechanism in the sense that one molecule of catalyst may induce the polymerization of many molecules of monomer. For example, in polycondensations it is certain that the polymer is built up step by step by a series of essentially similar reactions. Again, it is found in some reactions that, once started, they seem to proceed indefinitely provided monomer is continuously supplied to the growing polymer. The result is that the convenient and powerful stationary state method of analysis cannot be applied. Complexity reaches its peak when, to any one of these processes, are added the phenomena of the branching and subsequent cross-linking of the linear chains to form three-dimensional networks. Explosive or indefinitely rapid polymerization has not so far been observed, and hence the theory of branching chains provides no help at present.

It is therefore no mean task to devise methods which will yield quantitative information about the molecular statistics of so diverse a series of processes. The volume under review gives a description of the efforts that have been made in recent years to tackle some of these problems. The first part gives an account of the structure of high polymers and their physical and chemical characteristics. There follows next a comprehensive description of the experimental methods employed to trace the course of polymer reactions—a section which will be of particular interest, as the methods are manifold and widely scattered in the literature.

A considerable portion of Part 1 is devoted to the consideration of general reaction kinetics. This subject has received so much publicity that the newer material is at last finding its way into text-books and thus its reproduction here is not so necessary. On the other hand, it makes the volume complete in itself. Thereafter follows the theory of polymer reactions. Its particular form follows closely the presentation which has been adopted by Prof. Mark and his collaborators in previously published work. Here there are many controversial points, but since the assumptions made are often extremely difficult to check experimentally, there is no point in discussing the more detailed parts of the theory provided it is realized that modification in the near future is almost inevitable.

Reference is made in Part 1 to some of the experimental work on the kinetics of polymerization, but the main account of the behaviour of various types of monomer is reserved for Part 2, in which each individual reaction is considered separately and all the relevant facts brought to notice. While this is invaluable as a compilation, it is disappointing to anyone primarily interested in discovering just how far kinetic analysis may be pushed in the examination of these reactions. Many of the reactions have, of course, not been studied in such a way that the data are suitable for analysis, and therefore strictly should be excluded. On the other hand, this lack of knowledge serves to emphasize where further work is needed and what reactions are most likely to be amenable to kinetic discipline.

This volume is, in short, a survey of the beginnings of a new subject and is in no sense a description of a rigorously developed theory supported adequately by exact measurements. It must therefore be read in this spirit. Prof. Mark and Dr. Raff may be congratulated on having the courage to attempt to bring coherence into a fresh region of reaction kinetics.

H. W. MELVILLE.

SCIENCE AND INTERNATIONAL POLITICS*

By SIR RICHARD GREGORY, Bart, F.R.S.

It was with a certain amount of reluctance that I accepted the invitation to address the Royal Institute of International Affairs upon the subject of "Science and International Politics". My hesitation was largely due to views expressed in the public press and elsewhere, after the recent Conference in London on Science and World Order, as to the desirability or otherwise of keeping science and politics within the particular fields of action commonly assigned to them. The Conference was organized by the Division for the Social and International Relations of Science of the British Association.

As science is an international study, the intention of the organizers of the Conference was to have the subjects of the programme presented from a world point of view. So far as I know, this was the first occasion on which many leading representatives of science, politics, and sociology, from many different countries, assembled with the common object of understanding each other's attitudes towards the subjects brought forward. It is not surprising that relationships of science to systems of government and to social problems attracted great public attention to the Conference, and that there were differences of opinion as to the value to the community of close or loose contacts between them. In countries where all the forces of science belong to a State service, the pursuit of knowledge for its own sake is not an organic part of the scheme of action, however much satisfaction it may give to individuals who undertake it, or however valuable the discoveries made may prove ultimately to be. Where science is regimented, no distinction is made between academic and applied scientists, and operations are assigned to each in the plan of campaign. Team-work is organized in the service of the State instead of being left to sporadic initiative.

This system of State planning of the pursuit of scientific knowledge with practical purpose as the aim is responsible for the great advances in science and industry achieved in the U.S.S.R. in recent years; and it has supporters among men of science in Great Britain. The basis of the system is obviously communistic; and British men of science who approve of it are regarded as both scientific and political revolutionaries whose activities are a danger to scientific freedom. Liberty of thought, work and expression is highly cherished in the commonwealth of science, and in Great Britain no conditions which would limit it would be tolerated. As citizens, men of science have the right to hold any political or religious faith, and the duty also of justifying it when needed. The general view is, however, that they should not embarrass science by advocating doctrines which would make her the handmaid of a particular political party.

This view was expressed by Sir Henry Dale in his presidential address delivered at the recent anniversary meeting of the Royal Society. "I see danger", he said, "if the name of science, or the very cause of its freedom, should become involved as a battle cry in a campaign on behalf of any political system, whether its opponents would describe it as revolutionary or reactionary. If science were allowed thus to be used as a weapon of political pressure, it would be impossible to protect science itself from the pressure of sectional politics".

Sir Henry Dale's remarks led to correspondence in *The Times* on science and politics and the organization of research in the social sciences. No one suggested that an authority in a particular branch of natural science could be assumed to have expert knowledge and experience in the fields of the political and social sciences. On the other hand, it was acknowledged that these departments of civil life could with advantage make fuller and more systematic use of scientific methods of inquiry into the factors which determine human conditions and potentialities to-day.

By modern use, science has come to signify natural philosophy, or verifiable knowledge acquired by observation and experiment. When its field of work is thus defined, there is an impermeable membrane between science and politics. The partition is dissolved when science—the domain of reason—is defined as systematic and formulated knowledge in all fields of human understanding—natural, moral, social and political. At all stages of civilization, these factors have determined the conditions of human life in varying degrees; and in modern times scientific knowledge has been the chief element in the constitution of man's outlook and the greatest power for social and political action.

As science, using the word in the sense now generally understood, is kept apart from politics, it has little influence upon the uses to which its power is applied, whether for good or evil. In general, this influence is not given effective attention in political and social philosophies; and the attitude towards it to-day is much the same as that of Plato towards the results of observational and practical inquiry represented by the Ionian school, upon the principles of which physical science may be said to be founded. In Platonic politics, the State decided what was good for the peoples to know and accept, and the purpose of legislation was to ensure the stability of a society of rulers and slaves. The spirit of political Platonism still prevails, even though modern science and technology have placed a score of mechanical slaves at the disposal of every citizen in a modern State.

In the understanding of this increased power, and in action based upon it, political leaders can scarcely be said to take adequate account of the changing conditions of life due to applications of new scientific knowledge, either in the present or for the future. They are in charge of the forces of science, and upon them is the responsibility of seeing that these are used effectively for the progressive welfare of the community. In this relation to politics, the functions of science may be compared with those of an intelligence department which possesses knowledge of the equipment available everywhere for social or political development, but has no influence upon action derivable from it.

In a democratic State, the uses made of science, like those provided for defence or attack on land, sea and air, are decided by leaders elected by representatives of the people. If these representatives rarely include men distinguished for their contributions to useful knowledge, it is because such original investigators find the air of the research laboratory more congenial and productive than the turbulent atmosphere of politics. In the discussion of any subject, the value of the views expressed depends upon the first-hand knowledge possessed of it. This is as true of politics as it is of science, though in these two fields rhetoric and fact differ in their influence.

---

*Substance of an address delivered at the Royal Institute of International Affairs on Feb. 3.

As the forces of science are in action along the whole front of advancing civilization, it is essential that their strength and disposition should be given full consideration in all social and political campaigns. Their leaders have a right, and a responsibility to their colleagues as well as to other fellow-citizens, to share in the preparation of schemes of operation in which their forces are used. When they enter the field of politics, they possess at least as much general knowledge of the problems involved as is required of representatives of other interests, whether industrial, commercial and financial, or of the armed forces. Their views can have no special authority outside the scientific field to which they have devoted particular attention; but they may justly claim to have been trained to face facts before arriving at judgments, and the value of their public service depends upon their competence to transfer this faculty to the consideration of social and political problems.

One reason why few men of science care to take an active part in politics, is that they do not feel able to effect such a transfer of their trained habits of thought. Birth, social surroundings, and feeling largely determine the side taken in national politics, but all these have little to do with the making of scientific students and discoverers. It is only by applying to political problems the principles of independent inquiry and impartial judgment demanded of investigators in all branches of natural knowledge, that politics can become a science and scientific workers as such can contribute to its advancement. Without this spirit and purpose science and politics are best placed in separate categories.

There is, however, a vast difference between party politics of a national kind and international politics in which the world is the unit and all men are citizens of it, having rights and duties to be wisely adjusted with the object of ensuring progressive development everywhere. This is the field into which the international spirit of science can enter without being regarded as an intruder or becoming involved in controversial national politics. The world is the possession of man, and his endeavour should be to see that its resources, with the powers provided by science, are used for effective development. National boundaries have little relationship to the distribution of natural resources, and less to the needs of modern life. All communities can share in the achievements of scientific discovery and invention, and none can establish an exclusive right to the use of them. Radio communication and aviation have made it impossible for any one nation, or group of nations, to isolate itself from the others, whether near or far. There will be no need for any civilized community to strive for self-sufficiency in a single region, or within a political sphere of influence, when these world powers become agents of international politics. The way may be far to go before national interests will acquire an international outlook, yet the tendency of political groups to become larger gives promise of further expansion into a commonwealth of the chief free peoples of the world.

Such a commonwealth can be secured only by consent, and in it there will be no place for the mastery by force of one race or nation over another. No new world order can have stability unless each nation is free to follow its own lines of cultural development, and does not seek to deprive others of the same liberty. There can be patriotism without arrogance and unity without aggressive imperialism. What is wanted now is not pride of power to make one nation submit to the will of another, and the exercise of it to secure mastery of the world, but pride in a union upon the strength and structure of which each nation depends for freedom and security.

It is only with such a co-operative alliance in mind that the services of science can be used to shape the course of international politics. Knowledge of natural objects and phenomena—their properties, occurrence and range—is not confined to political regions, either in extent or in the use of it. This knowledge is free to the world, and is the foundation upon which the structure of modern civilization is based. It is continually revealing new sources of supply of materials, and power to expand this structure as well as to adorn it. Applied science has provided the means of making the world's abundance available to all peoples. The world is, indeed, self-sufficient to supply the needs of all mankind, and the aim of international politics should be to see that the supply is adjusted according to the need for the use of it.

In the fourth clause of the Atlantic Charter, Mr. Roosevelt and Mr. Churchill expressed the intention of the United States and the British Commonwealth to adopt this principle in a unified political policy. The clause declares that "they will endeavour, with due respect for their existing obligations, to further enjoyment by all States, great or small, victor or vanquished, of access, on equal terms, to the trade and to the raw materials of the world which are needed for their economic prosperity."

This Anglo-American declaration, with the power of two great democracies to implement it, gives an impressive outlook to a new world order. No federation of European States alone could make such a declaration of the effective value represented by the unification of purpose of the British and American Commonwealths. When the principle of freedom of access to the raw materials of the world is conceded by the chief nations of the world, the problems of international politics will be greatly simplified and science will become the chief factor in their solution.

What exists in the world, and what uses can be made of it, are discovered by scientific inquiry and its application. What action is taken upon the knowledge or power thus gained depends upon communities and their governments. Knowledge of natural forces and resources gives no control over them but only an understanding of cause and effect available for human service. Science as such is concerned with the advancement of natural knowledge, and its standards of value are neither ethical nor political. Men of science, therefore, make no special claim to express opinions upon political matters, except in so far as their pursuits affect the welfare of the community, and its repercussions with them. When, however, they give close attention to subjects outside the particular fields they have made their own, their reactions are at least as worthy of consideration as those of other enfranchised citizens.

The view that the sole function of men of science is to study and discover natural facts and principles without regard to the social implications of the knowledge gained can no longer be maintained. It is now widely acknowledged that science cannot be divorced from ethics or rightly absolve itself from the human responsibilities in the use of its powers in economic or political planning. Men of science neglect their duty if they continue to retain the monasterial habits which society commonly assigns to them, and are content to remain isolated from the structure of civilization built up from materials provided by them. It is their obligation as citizens to assist in the establishment of a rational and harmonious social order out of the welter of human conflict into which the world has been thrown because the powers they have released have not been rightly used in the services of mankind as a whole.

To suggest that the world is a single unit in which all men have certain fundamental rights to live and work, each according to his capacity and needs, may not be practical politics—national or international—yet these are the basic factors in the world's equation. Science and ethics should be able to agree as to the rights of all men to a place on this earth of ours and their duties to the community. Until international politics mean something more than a survey of national claims and actions, with no scientific or ethical principles upon which to arbitrate, expediency and not equity must continue to determine its judgments.

Before any worthy world order can be established, the fundamental rights of men and communities must be defined and acknowledged by the democracies which promote it. The Anglo-American Charter represents the beginning of the infusion of this spirit into the working of world affairs. The outlook of international politics is vastly extended by this Charter, and an instrument has been constructed which gives new meanings to the dimensions of time and space on a changing world. It recognizes by implication that the goal of a world commonwealth can be brought into sight and gives hope that the promise of a dream is not beyond fulfilment.

It was in this spirit that a Declaration of the Rights of Man was drafted a year ago by a committee under the chairmanship of Lord Sankey and submitted to public discussion. The opening paragraphs of the introduction to the Declaration may be appropriately reproduced here because they state world conditions differing from those with which international politics have hitherto had to deal. The paragraphs read as follows:

"Within the space of little more than a hundred years there has been a complete revolution in the material conditions of human life. Invention and discovery have so changed the pace and nature of communications round and about the earth that the distances which formerly kept the States and nations of mankind apart have now been practically abolished. At the same time there has been so gigantic an increase of mechanical power, and such a release of human energy, that men's ability either to co-operate with or to injure and oppress one another, and to consume, develop or waste the bounty of Nature has been exaggerated beyond all comparison with former times. This process of change has mounted swiftly and steadily in the past third of a century, and is now approaching a climax.

"It becomes imperative to adjust man's life and institutions to the increasing dangers and opportunities of these new circumstances. He is being forced to organize co-operation among the medley of separate sovereign States which has hitherto served his political ends. At the same time, he finds it necessary to rescue his economic life from devastation by the immensely enhanced growth of profit-seeking business and finance. Political, economic and social collectivisation is being forced upon him. He responds to these new conditions blindly and with a great wastage of happiness and well-being."

The object of the Declaration was to assemble and proclaim fundamental and inalienable rights of man as a species living upon the planet Earth, and with powers of conquest over agencies—natural or social—which obstruct his advancement. Science and the humanities can meet on common ground in an endeavour to make a charter of this kind represent elements which enter into human reactions and should be regarded almost as commandments for the guidance of international policies. When agreement has been reached upon the essential human needs and rights declared in such a charter, a very promising nucleus will have been created upon which scientific and ethical principles can crystallize. Without a foundation of this kind, conciliation of conflicting interests and political expediency will determine the influence and actions of leagues, unions, councils and courts, and there will be no fixed star by which to shape the courses of ships in the stormy seas of international politics.

Since the outbreak of the conflict in which all peoples of the world are now directly or indirectly involved, many declarations have been made of principles expressing the needs and aims of all men. They all have much in common, and from them it should be possible to construct fixed standards in which the rights of nations are given world values and the welfare of the whole community of mankind is the concern of international politics. However far distant we may be from the effective application of such basic principles, conditions of life to-day demand the formulation, by common consent, of a charter in which all communities will have world rights, relationships and responsibilities. There can be no unified political, economic and social order unless schemes of reconstruction are conceived in this spirit, with full knowledge of the primitive instincts of man and the lag between them and the powers which science have given him.

The three chief principles of inter-State intercourse, on which international law is based, are said with authority to be:

(1) Recognition of each other's existence and integrity as States.

(2) Recognition of each other's independence.

(3) Recognition of equality, one with another, of all independent States.

International law may narrate these principles, but international politics have made a mockery of them. A bewildered world finds itself deprived of all these 'recognitions', and seeks new fundamental truths to satisfy its outlook. The so-called laws of Nature are only generalizations which have to be revised when cases not covered by them are brought before the court of science. International politics has to adopt a similar attitude towards the evidence presented to it, and international statutes should not be limited to the relationships of one sovereign State to another, but of every State to all others.

In the realm of the humanities, as in that of the natural sciences, the closer the approach of a principle to fundamental truth, the longer will it survive. All peoples of the world have certain attributes in common, and all high religions teach the observance of certain ethical principles. When these principles have been analysed and collated, a sound basis will be secured for the constitution and judgments of a court of international politics, and the goal of world unity will come into view. Science can usefully combine with politics to attain this end.

GROWTH AND DETERMINATION IN THE DEVELOPMENT OF DROSOPHILA

By Dr. C. H. WADDINGTON
Department of Zoology, and Strangeways Research Laboratory, Cambridge

It is usually held that development in the Diptera is typically 'mosaic'. The determination of larval characters is known to take place at a very early stage (reviewed, Richards and Miller[1]), and that of the imaginal characters is not supposed to be delayed more than a few hours after fertilization. The evidence on which the latter part of this statement is based is not extensive. Geigy[2] observed the development of defects in Drosophila flies which had been injured by ultra-violet puncture shortly after fertilization, and Howland and Child[3] obtained similar results with mechanical injuries. Pursuing another line of experimental analysis, the workers with the transplantation technique of Beadle and Ephrussi have shown that the imaginal buds of the eye region, isolated from young larvæ, are able to develop well-formed ommatidia when isolated in the body cavity of host animals. Steinberg[4] has pushed back the earliest time from which successful development is possible to twenty-four hours after hatching, before which the buds are too small to be handled.

The history of the analysis of amphibian development is a warning of the danger of considering such defect or isolation experiments as satisfactory means of discovering the developmental potentialities of tissues; many cases are known in which, although defects are not made good, or 'self-differentiation' occurs after isolation, the tissues have later been shown to be still labile and capable of being deflected into quite a different developmental path. Some recent work on Drosophila indicates that a similar error of interpretation has been made in respect of the imaginal buds of that form.

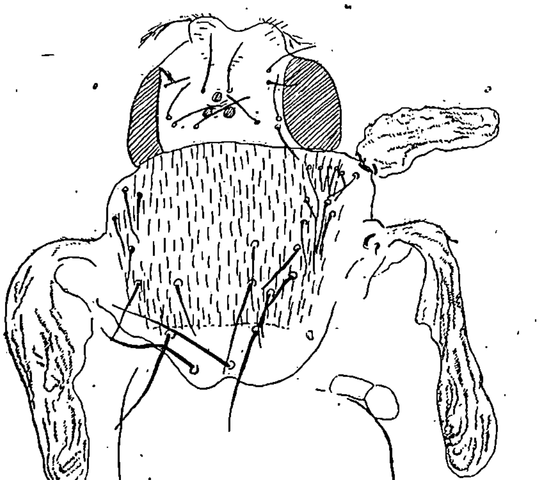

Fig. 1.
DROSOPHILA ADULT, X-RAYED AS LARVA AGED 66-72 HOURS AFTER LAYING. NOTE REDUPLICATION OF WING-BEARING REGION OF THORAX ON RIGHT SIDE.

Drosophila larvæ were treated with heavy doses (7,000 r-units) of X-rays. Pupæ aged more than twenty-four hours after puparium formation when irradiated showed little or no morphological effects. Irradiation in the period between twelve hours before and eighteen hours after puparium formation caused the death of large numbers of individual cells. This led to the cessation of morphogenesis in the wings at an early stage, but its most marked effects were on the chætal elements. Large numbers of bristles, both macro- and micro-chætæ, were removed; the macro-chætæ were more strongly affected towards the beginning of the period and the micro-chætæ towards the end. In Drosophila each bristle is accompanied by a socket, the complete apparatus being formed from a group of two cells. The proportion of cases in which both cells were removed was much greater than would be expected if the only effects were the direct results of ionizations; one must conclude that the two cells influence one another during development, and that the death of one is likely to prevent the differentiation of the other.

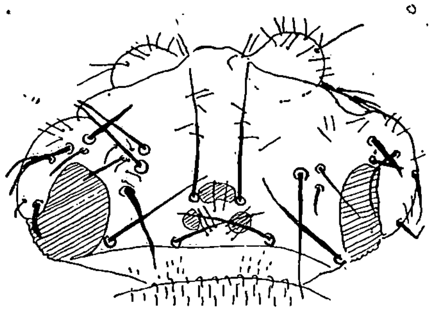

Fig. 2.
X-RAYED AS 72-90 HOUR LARVA. NOTE PALPS ON BOTH EYES.

The most interesting results were obtained with irradiations of larvæ aged 60–90 hours after laying, that is, in the early part of the third instar. The mortality was very high, and no flies succeeded in emerging from the pupa cases; those which did develop had to be freed from their pupal integuments by dissection. In most of them, various organs were found to be hypertrophied; and the increases in size of the parts were often accompanied either by reduplication or by the development of tissue characteristic of some other part of the body. The antennæ were little affected, although in one case the base of the arista was transformed into a somewhat leg-like material. The eyes, on the other hand, were very frequently abnormal; they were usually larger than normal, and the anterior dorsal region was transformed into a palp bearing typical bristles, and this might be lengthened into a band cutting the whole eye into two parts, which should probably be regarded as two separate eyes developed by reduplication. In a few cases the palp had the character of an antenna. Overgrowth in the thorax led either to duplication of some regions (for example, the scutellum or the wing-bearing region) or merely to the formation of an irregular and lumpy thorax. Within the wing itself, extra lobes might be formed, or part of the wing might be converted into a tissue resembling the normal body surface. The legs were highly abnormal, often sharply bent and very swollen.

Larvæ much younger than sixty hours at irradiation gave rise to completely normal adults. We therefore find that the developmental fate of imaginal buds can be changed as late as ninety hours after laying, while earlier than sixty hours determination is so indefinite that complete regulation is still possible. The agent by which these changes have been produced (7,000 r-units of X-rays) is, of course, a drastic one, but the effects produced cannot be considered to be merely injuries (for example, the conversion of eye material into antenna). We must conclude that changes in developmental fate can be caused by factors which can be produced, under the influence of X-rays, by the tissues themselves. It becomes then a reasonable hypothesis to suppose that determination in normal development is brought about by similar tissue interactions; and one is inevitably reminded of the organizer phenomena in vertebrate embryology.

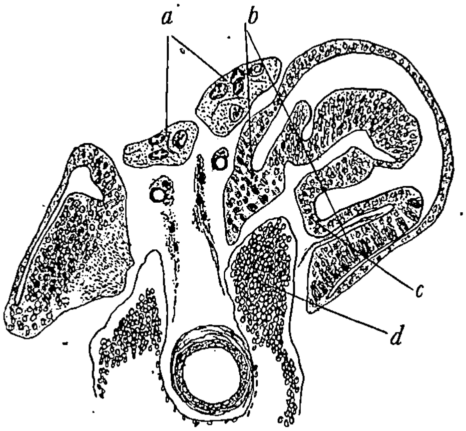

Fig. 3.

SECTION THROUGH IMAGINAL BUD OF RIGHT EYE IN LARVA X-RAYED WHEN AGED 72–90 HOURS. *a*, WEISSMAN'S RING; *b*, EYE-FORMING REGION OF IMAGINAL BUD; *c*, FOLD IN BUD, WHICH WILL GIVE RISE TO PALP; *d*, ANTERIOR PART OF BRAIN.

The nature of the determining factors produced by the irradiation cannot be stated with certainty, but it is clear that changes in growth are intimately involved with them. This is so not only in the cases where an obvious hypertrophy has occurred as in the reduplicated organs, but also in connexion with the palp-formation in the eyes. In the cephalic imaginal buds of irradiated larvæ just before pupation a fold can often be found in the eye-forming region, and it seems certain that this is (*a*) a result of an overgrowth of this region, and (*b*) the forerunner of a palp. An exactly similar appearance can be found in the imaginal buds of larvæ homozygous for the gene *ophthalmopedia* (stocks of which I owe to the kindness of Dr. C. Gordon), which causes the formation of eye-palps very similar to those in the irradiated flies.

There is evidence from another quarter which strongly suggests that abnormalities of growth, by causing irregularities of the folding of the imaginal tissue, eventually bring about changes in differentiation. Several genes are known which affect the legs of Drosophila; *dachs* and *fourjointed* shorten the legs and reduce the number of tarsal joints to four, *dachsous* produces somewhat irregular short legs, and *comb-gap* (derived from an *S E-S/cg l* stock obtained from Muller; possibly two closely linked genes are concerned in the variable effects noted here) causes the legs to be irregularly swollen, sometimes very considerably. All these genes have secondary effects; that of *comb-gap* is the production of a gap in the fourth longitudinal vein on the wings, but in the others the effects clearly involve growth, the wings being reduced in size and made rounder, the thorax made short and thick, etc. The leg effects, which are the most easily recognized, can easily be detected in the imaginal buds at the time of pupation. None of the genes produces any changes in tissue differentiation when alone, nor do most of the compounds; homozygous *dachs-fourjointed* look the same as *dachs*, while in *dachsous-combgap* the leg buds are highly abnormal and frequently, owing to faulty eversion and failure of the subsequent contraction, produce legs more like flippers than normal Dipteran limbs. But very different phenotypes are produced by *dachs-dachsous* or *fourjointed-combgap*. In both cases reduplications and changes in differentiation are quite frequent; the antennæ are often double, and parts of the eye may be converted to antennæ (five antennæ on one head is the maximum number so far recorded), the blade of the wing may have extra lobes, or be duplicated in part, the whole wing region may be converted into typical body-surface, the legs may terminate in arista-like tufts, etc. In the case of the eye, abnormal folding, presumably the forerunner of antenna-formation, has been detected in the imaginal bud.

We have then two cases of two genes, each of which affects the growth of many parts of the fly, producing when in combination effects not only on growth but also on the type of differentiation undergone by the various imaginal buds. It is scarcely plausible to suggest that several different morphogenetic substances are involved, and that the genes when in combination, but not when alone, affect all these substances by some mechanism other than through their growth-effects. After accepting the evidence of the irradiation experiments that Drosophila imaginal buds remain incompletely determined throughout the greater part of larval life, much the simplest hypothesis is to suppose that their determination can be affected by abnormal folding, which can be produced by irregularities in growth.

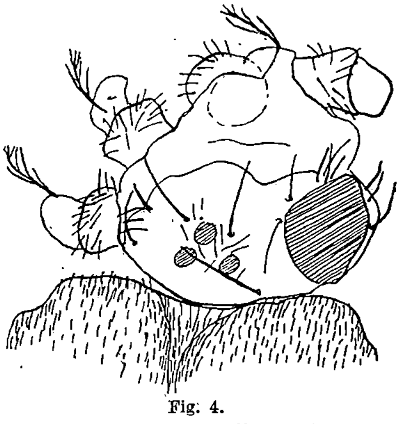

Fig. 4.

HEAD OF ADULT OF GENOTYPE *cg c fj px sp* (THAT IS, *combgap-fourjointed*). NOTE CONVERSION OF EYE TO ANTENNA, AND SWELLING OF THORAX.

OBITUARIES

Prof. T. Levi-Civita, For. Mem. R.S.

TULLIO LEVI-CIVITA was born at Padua on March 29, 1873, son of a renowned advocate who was mayor of Padua and senator of the realm. He entered the University of his native city where, after studying with Veronese and Ricci, he graduated in 1894; four years later he was appointed to the professorship of mechanics at Padua. In 1914, he married Sig.na Libera Trevisani, one of his former students. In 1918, he was called to the University of Rome, where he occupied the chair of theoretical mechanics until his dismissal, in 1938. He died in Rome, after a lingering illness, on December 29.

Levi-Civita was unquestionably one of the best-equipped and most versatile mathematicians of our time: primarily an applied mathematician, he had been strengthened by the magnificent discipline of the Italian geometrical school which, apart from inspiring his valuable researches in differential geometry proper, furnished him with powerful weapons for attacking the problems of physical science. In the latter field his interests were all-embracing, and he made important contributions to such diverse topics as potential theory, wave motion, hydrodynamics, analytical dynamics, relativity theory, thermodynamics and theoretical physics, in particular, quantum mechanics. On the more technical side, where he was often called into consultation by his colleagues, he studied various complex problems in electrodynamics, elasticity and strength of materials, devising practical methods of calculation which have since proved their worth.

In the field of pure mathematics his interest was scarcely less extended. One may mention that his first papers were on the distribution of prime numbers and the foundations of geometry; afterwards, as a natural outcome of his other work, he was drawn to the study of conformal representation—in which, as regards its applications, he was one of the pioneers—and the theory of partial differential equations. He also made one of the earliest contributions to the theory of functions of two complex variables: all this, be it observed, in addition to the work in differential geometry for which he is chiefly celebrated.

At this point it is interesting to recall that Levi-Civita's teacher, Ricci, was once refused a Royal Prize for his work on tensor calculus, on the ground that it could not conceivably be of use to anyone, even a differential geometer. An apt comment on this verdict was later to be provided by Einstein's general theory of relativity, the foundations of which were actually laid in a great memoir by Ricci and Levi-Civita themselves. However, both before and after the tensor calculus had become useful, Levi-Civita was its most assiduous cultivator; and during a long period the *Rendiconti* of the Lincei were enriched by a series of notes on differential geometry, treated by its methods. These researches culminated in the memoir of 1917, introducing the concept of parallelism with which his name is associated, and constituting perhaps his surest title to fame.

The fecundity of such a great and varied production is amply proved by the number of disciples who have followed in its wake and the schools which have found inspiration in its conceptions. This multiform activity was centred, not in the published work, but directly in its creator. For more than forty years Levi-Civita was one of Italy's greatest teachers, drawing to himself students from all over the world, aiding and encouraging them with inexhaustible patience and generosity. Part cause, part effect of these contacts was a knowledge of mathematical literature that was truly encyclopædic; until the end Levi-Civita maintained his grasp of nearly the entire range of contemporary mathematics, and with his reading went a vast scientific correspondence, to which he attended with his customary diligence and zeal. As a writer of text-books, Levi-Civita is mainly known in Great Britain by the English version of his work on the tensor calculus; but it should be added that his comprehensive treatise on mechanics (written in collaboration with Amaldi) is the leading Italian work on the subject. A course of lectures on differential systems and wave propagation has also been published in book form.

Nevertheless, however splendid his achievement, to those who have known him it must always take second place to the man himself. This cannot often be said of a mathematician; not to say it of Levi-Civita would be unjust to his memory. The exquisite courtesy, the humility carried to such lengths that it might have been judged hypocrisy in another, were typical manifestations of his generous spirit. Many will have received some special token of his kindness; many more will have enjoyed his hospitality, or carry with them the indelible souvenir of his presence in the lecture room: the characteristic figure on the rostrum expounding, with overwhelming enthusiasm, some point in the theory of mechanics or differential equations.

Levi-Civita was the recipient of many academic distinctions and honorary member of numerous societies, in particular, of almost all the scientific academies of Italy and Germany. In 1938, when dismissed from his post in consequence of the racial legislation, he was also expelled from the latter, with the sole exception of the Pontifical Academy of Sciences. In Italy itself his death occasioned no official response, save within the Vatican City, where, at a recent session of the Pontifical Academy, he was duly commemorated. His last years had been overcast by an ever-deepening pre-occupation with the future of his country; it is easy to imagine how so liberal a mind, coloured with the Garibaldian traditions of his early education, viewed the progressive decay of international relations and ethical standards. With his death there has passed away a man of science and an Italian whom we can ill afford to lose and whom we shall not soon see replaced.

L. ROTH.

Dr. A. K. Chalmers

WE regret to announce the death at the age of eighty-six of Dr. Archibald Kerr Chalmers, one of the most eminent contemporary epidemiologists. He was born at Greenock in 1856, and received his medical education at Glasgow, to which he remained faithful, and qualified in 1879. After holding resident appointments at the Glasgow fever hospital, he was appointed medical officer of health for that city in 1892, and held the office until his retirement in 1925. Throughout his life he showed a remarkable administrative and literary activity. During his term of office he was busily engaged in the management of acute infectious diseases. Besides Chalmers's principal work entitled "Health of Glasgow, 1818–1925: An Outline" (1930), which may be regarded as a classic, he was also author of addresses on several sanitary subjects, such as "Vital Statistics of School Ages" (1898), "The House as a Contributory Factor in the Death-Rate" (1913), "Economy in Food during the War" (1915), and in 1924 delivered the Watsonian Lectures before the Faculty of the Royal College of Physicians and Surgeons of Glasgow on "Epidemic Diseases of the Central Nervous System".

Chalmers received many well-merited honours, such as those of honorary LL.D. of Glasgow, honorary fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow and the Médaille du Roi Albert. He was president of the Section of Epidemiology and State Medicine of the Royal Society of Medicine in 1920.

J. D. Rolleston.

We regret to announce the following deaths:

Sir Robert Chapman, C.M.G., professor of engineering in the University of Adelaide during 1907–37 president of the South Australian School of Mines aged seventy-five.

Sir Robert Elliott-Cooper, formerly president o the Institution of Civil Engineers, on February 16 aged ninety-seven.

Prof. Max Kriss, associate professor of animal nutrition in Pennsylvania State College, aged fifty-two.

Dr. Paul S. McKibben, professor of anatomy and dean of the School of Medicine of the University of South California, known for researches on the nervous system of Amphibia, aged fifty-five.

The Very Rev. Sir George Adam Smith, F.B.A., Principal of the University of Aberdeen during 1909–35, on March 3, aged eighty-five.

NEWS and VIEWS

Prof. A. C. Hardy, F.R.S.

Prof. A. C. Hardy, whose appointment to the regius chair of natural history in the University of Aberdeen has just been announced, is well known for his distinguished work on plankton problems. The development of the strikingly new methods which he has evolved in this work may be traced to the time when, as a member of the scientific staff of the Ministry of Agriculture and Fisheries, he introduced a simple plankton recorder made to assist fishermen in the location of herring shoals. Later, as second-in-command on the scientific staff of the Discovery Committee, he spent some two years in the Antarctic in the R.R.S. *Discovery*, and here had opportunities for the invention of a much more elaborate instrument designed to give a continuous record of the plankton, while being towed at full speed. Undeterred by initial failures he finally perfected this instrument, and from the new department which he later founded at University College, Hull, he inaugurated comprehensive plankton surveys of the North Sea with plankton recorders used from commercial vessels. This work, with Government assistance, developed rapidly until the War made it necessary to discontinue operations at sea; a substation was opened at Leith and a number of very valuable reports have appeared in the *Hull Bulletins of Marine Ecology*.

It is satisfactory to learn that Prof. Hardy's fruitful work on the North Sea plankton will continue. On taking the chair at Aberdeen he will become honorary director of oceanographical investigations at University College, Hull, and the oceanographical work of that department will henceforth be in charge of Mr. C. E. Lucas, the senior member of his research staff. In addition to this profitable work on plankton, Prof. Hardy has most ingeniously adapted oceanographical methods to the study of insect distribution. Using devices similar to those employed under water, he has flown light nets, fitted with opening and closing mechanism, from kites; and in this way has shown that many species of insect, including agricultural pests, can be brought to Great Britain in the upper layers of the air.

Royal Society of Edinburgh

The following have been elected ordinary fellows of the Royal Society of Edinburgh:

Prof. T. Alty, Department of Applied Physics, University, Glasgow; Mr. R. E. Cooper, curator, Royal Botanic Garden, Edinburgh; Dr. James Cossar, lecturer in technical mathematics, University, Edinburgh; Prof. T. Dalling, director, Ministry of Agriculture's Veterinary Laboratory, Weybridge; Dr. S. C. Das, lecturer in pharmacology, Robertson Medical School, Nagpur, C.P., India; Dr. Andrew Davidson, chief medical officer, Department of Health for Scotland; Mr. Arthur Earland, Edinburgh; Dr. G. H. Edington, Glasgow; Mr. A. H. Gosling, assistant commissioner, Forestry Commission, Scotland; Prof. A. Gray, Department of Political Economy and Mercantile Law, University, Edinburgh; Dr. R. A. R. Gresson, Department of Zoology, University, Edinburgh; Dr. K. E. Grew, lecturer in physics, Heriot-Watt College, Edinburgh; Dr. W. A. Harwood, superintendent, Meteorological Office, Edinburgh; Dr. J. R. M. Innes, pathologist, Biological Laboratories, I.C.I. (Dyestuffs) Ltd., Hexagon House, Manchester; Dr. Daniel Lamont, surgeon, Glasgow Royal Cancer Hospital, and Glasgow and West of Scotland Radium Institute; Dr. W. M. Levinthal, bacteriologist, Royal College of Physicians Laboratory, Edinburgh; Dr. James Macfarlane, medical liaison officer, Scottish Office, London; Mr. Peter N. McFarlane, Glenordie, Stanley, Perthshire; Dr. J. F. Malcolm, lecturer in bacteriology, West of Scotland Agricultural College, Glasgow; Prof. S. T. Mayow Newman, Reid School of Music, University, Edinburgh; Dr. Jocelyn Patterson, lecturer in biochemistry, Charing Cross Hospital Medical School; Dr. J. R. Peddie, secretary, Carnegie Trust for the Universities of Scotland; Mr. Douglas M. Reid, senior biology master, Harrow School; Prof. W. J. B. Riddell, Department of Ophthalmology, University, Glasgow; Dr. J. D. Robertson, Courtauld Institute of Biochemistry, Middlesex Hospital, London; Dr. William Scott, Fryern Hall, Bridgewater, Somerset; Mr. Charles Strachan, lecturer in applied mathematics, University, Liverpool ; Dr. Joseph Tait, resident secretary in Scotland, Pharmaceutical Society ; Mr. D. R. Wilson, bacteriologist, Moredun Institute, Animal Diseases Research Association, Gilmerton, Edinburgh.

The Council of the Royal Society of Edinburgh has awarded the Keith Prize for the period 1939–41 jointly to Prof. E. T. Copson, University College, Dundee, and to Prof. W. H. McCrea, Queen's University, Belfast, for their papers in the *Proceedings* of the Society within the period of the award, and in recognition of their valuable contributions to the theory of Riemannian space and general relativity.

The Neill Prize for the period 1939–41 has been awarded jointly to Dr. P. C. Koller, Institute of Animal Genetics, University of Edinburgh, for his contributions to cytology ; and to Dr. W. J. McCallien, Department of Geology, University of Glasgow, for his contributions to the tectonic geology of the Scottish Highlands.

Philosophy of the Physical Sciences
